Introduction to Measure and Probability

J.F.C. KINGMAN and S.J. TAYLOR

The theory of finite measures in general spaces is presented as a background to an account of the fundamental theoretical ideal underlying the application of probability in statistics and elsewhere.

'The authors have succeeded in producing a very useful addition to the literature, which will be a standard text for many years to come.'

Journal of the London Mathematical Society

£5.20 net

RP374

Introduction to Measure and Integration

S. J. TAYLOR

A paperback edition of chapters 1 to 9 of Introduction to Measure and Probability, by J. F. C. KINGMAN and S. J. TAYLOR.

A book for advanced undergraduate and graduate students of mathematics, statistics and physics in universities and technical colleges.

Paperback £1.90 net

A First Course of Homological Algebra

D. G. NORTHCOTT

About fifteen years ago homological algebra was considered a new subject but since then it has found many applications. Professor Northcott has produced a treatment which proceeds rapidly to a variety of applications that illustrate what the subject has to offer and stimulate the interest of the young mathematician.

The book includes many exercises and can be used as a course text for graduate students and final year undergraduates. It also contains some previously unpublished material that will interest the specialist.

£4.50 net

The Pituitary Gland— A Comparative Account

R. L. HOLMES and J. N. BALL

The pituitary gland, as the source of many hormones, enables the central nervous system to control a wide range of body functions. This account presents a broadly based comparative study of the pituitary in all the vertebrates from fish to man.

The authors present a critical survey of the vast body of information now available for anatomists, medical scientists, zoologists, endocrinologists, physiologists and biochemists. Everyone concerned with the pituitary will find much that is of value here.

£10.00 net

Topological Riesz Spaces and Measure Theory

D. H. FREMLIN

A book for functional analysts who need to understand better the application of measure theory to their own discipline. The relationship of the two subjects has not always been easy, but Dr. Fremlin identifies and explains those concepts in measure theory most relevant to functional analysis in a form accessible to beginning graduate students. This is achieved by approaching measure theory through the properties of Riesz spaces and especially topological Riesz spaces.

£5.90 net

Gas Transfer in the Lung

B. A. HILLS

An account of the processes involved in the transfer of gases between the body environment and blood, via the lungs or gills.

Dr. Hills' treatment, although adopting a strongly mathematical and physical approach, includes an explanation of the underlying concepts which will meet the needs of both the aspiring respiratory physiologist seeking an introduction to the subject and also the established worker who wishes to adopt a more analytical basis for the interpretation of his work.

Guide to authors

Nature accepts three types of communications:

- Articles are up to 3,000 words in length with at most six figures and may either be reports of major research developments in a subject or broader reviews of progress.

- Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four figures.

- 'Matters Arising' permits occasional short discussion of papers that have previously appeared in *Nature*. A limit of 350 words is placed on contributions in this category.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système Internationale*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible. *exp (a)* is preferred to *e^a* if 'a' is more than one character. Articles should be accompanied by an abstract of not more than fifty words, and the abstract should list the main conclusions that are drawn.

References are indicated by superscripts in the text. The style may be gleaned from any contemporary *Nature* with the following two changes:

(i) If it is necessary to refer to several references by the same author at once, only one reference number need be given.

(ii) The last page as well as the first of any reference should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963-65). 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript. All artwork should be marked with the author's name. Line drawings should preferably be in Indian ink on heavy cartridge paper, although other materials are acceptable; thin, shiny, folded, torn or heavily handled material should be avoided. Matt rather than glossy photographs are preferred. Figures are usually reduced to one column width. The originals should be about twice their final size. Figures, particularly maps, should contain nothing but essential material. It is preferred that the original be unlabelled, but with a copy containing lettering. Labelling on photographs should if possible be avoided entirely. The artwork of published papers can only be returned if a self-addressed envelope is enclosed.

A fuller guide appeared in *Nature* (246, 238; 1973).

FOOD ANALYSIS

60 secs or 60 minutes

The choice is yours

Today Atomic Absorption Spectroscopy enables the analysis for trace elements in foodstuffs to be performed with unprecedented ease. This technique brings a completely new dimension to this field of analysis.

For example, the determination of arsenic by the Gutzeit method is sensitive but time consuming, the final colour development alone taking up to 60 minutes. By measuring directly Perkin-Elmer's atomic absorption spectrophotometers and accessories reduce this to 60 seconds.

If your problem is arsenic analyses in foodstuffs, Perkin-Elmer's new Electrodeless Discharge Lamps (EDL's) offer the best sensitivity and detection limits available. Compared with the equivalent hollow cathode lamps, the arsenic EDL gives almost twice the sensitivity, ten times the brightness and achieves at least a fivefold improvement in detection limits (Fig. 1). When used with the H.G.A. Graphite Furnace the EDL is capable of analysing $0.01 \mu\text{g/ml}$ of arsenic in a sample of $20 \mu\text{l}$. This detection limit is better than 0.2 p.p.b. in a $100 \mu\text{l}$ sample. Please write today for further information on how Atomic Absorption and EDL's can help solve your food analysis problem.

SCHERING WORKSHOP ON CONTRACEPTION:

The Masculine Gender

Gerhard Raspé

339 pages £7.75 hard cover

CONTENTS:

Becoming a male; The behavior of chromosomes; Progress in the development of hormone-based contraceptives for the human male with the laboratory rat as a model; Feedback regulation of gonadotrophins in the male; Blood supply to testes and excurrent ducts; Observations on the organization of the interstitial tissue of the testis and on the occluding cell junctions in the seminiferous epithelium; The entry of antifertility and other compounds into the testis; Longitudinal growth of the seminiferous tubules in rats and its hormonal control; The epididymis as a possible site for control of fertility in the male; Components of sperm maturation in the human epididymis; Metabolism of spermatozoa with particular relation to the epididymis; Review on metabolic and enzymic studies of spermatozoa from the ampullae ducts deferentiae of bulls; Mechanisms of sperm transport in the male and female tract; Preliminary studies on the effects of cyproterone acetate on sexual activity and testicular function in adult male rhesus monkeys (*macaca mulatta*); Monitoring sexual activity—methods for measuring natural coitus; Human sexual inadequacy—behavior therapy and the Masters and Johnson Technique; Equality—in society, in family, in bed; The place of the seasonal breeder in research on male reproduction; Rationale for a screening program for anti-fertility compounds; Idle thoughts of idle pharmacologists; Sperm ultrastructure as an indication of sterility; Proteinases and proteinase inhibitors in the fertilization process: new concepts of control?; Condoms and things; Conceptual contraception; The manifesto.

Progress in Neurobiology

Volume 2 Part 3

G A Kerkut & J W Phillis

92 pages 10 illustrations

£2.50 flexi cover

Contents:

Axoplasmic transport *Peter L Jeffrey & Laurence Austin*; The release of acetylcholine from the brain: an approach to the study of the central cholinergic mechanisms *G Pepeu*

Biology and Neurophysiology of the Conditioned Reflex and its Role In Adaptive Behaviour

Peter K Anokhin

592 pages 158 illustrations

£17.00 hard cover

Contents: (partial)

The biological roots of the conditioned reflex; The nature of the unconditioned reflex; Systemogenesis as an evolutionary basis for the development of unconditioned reflexes; Recent theories on the coupling of the conditioned reflex; The hypothesis of the convergent coupling of the conditioned reflex; The functional system as a basis of the physiological architecture of the behavioral act; Conditioned (internal) inhibition: statement of a problem, approaches to its solution; The concepts of Sechenov, Vvedenskii and Ukhtomskii concerning the origin of inhibition in the central nervous system.

ARTICLES

Evidence for a ~ 4.5 aeon age of plagioclase clasts in a lunar highland breccia— <i>E. K. Jessberger, J. C. Huneke and G. J. Wasserburg</i>	199
Evidence for continental crust beneath the Faeroe Islands— <i>M. H. P. Bott, J. Sunderland, P. J. Smith, U. Casten and S. Saxov</i>	202
Direct physical evidence for secondary structure in an isolated fragment of R17 bacteriophage mRNA— <i>J. Gralla, J. A. Steitz and D. M. Crothers</i>	204

LETTERS TO NATURE—Physical sciences

Are binary systems involved in supernova explosions always disrupted?— <i>W. Sutantyo</i>	208
Internal rotation of the Sun and the solar neutrino flux— <i>I. W. Roxburgh</i>	209
Light curves of very faint meteors— <i>J. Jones and R. L. Hawkes</i>	211
Strong long-period tropospheric and stratospheric rhythm in the Southern Hemisphere— <i>P. J. Webster and J. L. Keller</i>	212
Dispersion of ionospheric waves— <i>T. J. Herron</i>	213
Will another damaging earthquake occur in Koyna?— <i>H. K. Gupta and B. K. Rastogi</i>	215
Gradient of caesium in the ocean— <i>T. R. Folsom</i>	216
Change in the current regime in the Suez Canal after reconstruction of Aswan High Dam— <i>E. M. Hassan and M. I. El Sabh</i>	217
Reply— <i>S. A. Morcos</i>	218
Time-dependent viscosity effects measured on an impact microviscometer— <i>G. R. Paul and A. Cameron</i>	219
Surface structures of gibbsite goethite and phosphated goethite— <i>J. D. Russell, R. L. Parfitt, A. R. Fraser and V. C. Farmer</i>	220
Gravitational charge, hadron hydrodynamics and Gödelised hadrons— <i>A. J. Fennelly</i>	221

LETTERS TO NATURE—Biological sciences

Specific recognition of the isolated R17 replicase initiator region by R17 coat protein— <i>J. A. Steitz</i>	223
High resolution proton NMR study of an isolated fragment of R17 bacteriophage mRNA— <i>C. W. Hilbers, R. G. Shulman, T. Yamane and J. A. Steitz</i>	225
Effect of camptothecin on simian virus 40 DNA— <i>L. Rubinstein and A. Rein</i>	226
Localisation of monocyte binding site of human immunoglobulin G— <i>G. O. Okafor, M. W. Turner and F. C. Hay</i>	228
Antibody response and virus survival in cats vaccinated against feline leukaemia— <i>W. Jarrett, L. Mackey, O. Jarrett, H. Laird and C. Hood</i>	230
Two distinct types of capping of surface receptors on mouse lymphoid cells— <i>C. W. Stackpole, J. B. Jacobson and M. P. Lardis</i>	232
T cell factor which can replace T cells <i>in vivo</i> — <i>M. J. Taussig</i>	234
Demonstration of suppressor T cells in a population of 'educated' T cells— <i>M. J. Taussig</i>	236
Cyclic GMP response <i>in vivo</i> to cholinergic stimulation of gastric mucosa— <i>J. H. Eichhorn, E. W. Salzman and W. Silen</i>	238
Colchicine and vinblastine inhibit fibroblast aggregation— <i>A. W. Waddell, R. T. Robson and J. G. Edwards</i>	239
Explanation of degree of correlation of sibling generation times in animal cells— <i>P. D. Minor and J. A. Smith</i>	241
Autosomal recessive mutation in sugar response of <i>Drosophila</i> — <i>K. Isono and T. Kikuchi</i>	243
Blood glucose and nutritive, antibiotic activity in ruminants— <i>R. Leskova and H. Zucker</i>	245

Guide to authors

Nature accepts three types of communications:

- Articles are up to 3,000 words in length with at most six figures and may either be reports of major research developments in a subject or broader reviews of progress.

- Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four figures.

- 'Matters Arising' permits occasional short discussion of papers that have previously appeared in *Nature*. A limit of 350 words is placed on contributions in this category.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible. $\exp(a)$ is preferred to e^a if a is more than one character. Articles should be accompanied by an abstract of not more than fifty words, and the abstract should list the main conclusions that are drawn.

References are indicated by superscripts in the text. The style may be gleaned from any contemporary *Nature* with the following two changes:

(i) If it is necessary to refer to several references by the same author at once, only one reference number need be given.

(ii) The last page as well as the first of any reference should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963-65). 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript. All artwork should be marked with the author's name. Line drawings should preferably be in Indian ink on heavy cartridge paper, although other materials are acceptable; thin, shiny, folded, torn or heavily handled material should be avoided. Matt rather than glossy photographs are preferred. Figures are usually reduced to one column width. The originals should be about twice their final size. Figures, particularly maps, should contain nothing but essential material. It is preferred that the original be unlabelled, but with a copy containing lettering. Labelling on photographs should if possible be avoided entirely. The artwork of published papers can only be returned if a self-addressed envelope is enclosed.

A fuller guide appeared in *Nature* (246, 238; 1973).

Structural difference between luminal and lateral plasmalemma in pancreatic acinar cells—P. De Camilli, D. Peluchetti and J. Meldolesi	245
Heterotransplantation of human foetal organs to the mouse mutant <i>nude</i> —C. O. Poulson, N. E. Skakkebaek, J. Rygaard and G. Jensen	247
Efferent control of cricket giant fibres—R. K. Murphey and J. Palka	249
Chloride-related depolarisation of crayfish muscle membrane induced by L-glutamate—T. Hironaka	251
Extracellular currents from frog photoreceptors—W. Ernst, W. S. Jagger and C. Baumann	253
Nematode growth factor—J. R. Vanfleteren	255
Depression of morphine-seeking behaviour by dopamine inhibition—A. S. Schwartz and P. L. Marchok	257
Appearance of unusual mitochondria in rice coleoptiles at conditions of secondary anoxia—B. B. Vartapetian, I. N. Andreeva and A. L. Kursanov	258
Dynamics of brachiating siamang [<i>Hylobates (Symphalangus) syndactylus</i>]—J. Fleagle	259

Precision Instruments

We now have capacity for aluminising certain types of mirrors, at short notice.

SOLE DISTRIBUTORS IN U.K. OF SCHOTT INTERFERENCE FILTERS

Polarimeter Model P.70

A long time has been spent developing this photo-electric polarimeter, and we are now satisfied that it will please the most discerning user. It has the accuracy of rotational measurement that can only be achieved from a ruled circle, plus independent magneto-optical compensation for recording or digital presentation, should it be required.

There are four models from which to choose, all virtually identical in external appearance, but with internal variations to provide the particular facilities that you require.

Full details from the manufacturers:

The SCORAH Automatic Electric all glass WATER STILL (patented)

Automatic Can be left on without attention. Heater current cuts off if water supply is interrupted, or inadequate or forgotten. When receiver (5 litres capacity) is full, current cuts off. When distilled water is drawn from receiver, the still resumes operation until receiver is refilled.

Purity Electrostatically charged condenser droplets can pick up fumes, dust and air-borne organisms from the laboratory atmosphere. The design of the receiver vessel ensures absence of such contamination.

Efficiency Heater of Scorah design and manufacture, consumption 1,700 watts, output 2.4 litres per hour (the full theoretical yield). Cost less than 2p per gallon at 1p per unit.

Safety The heating element is out of contact with the feed water, thus eliminating danger from "live" water supply or electrolytic effects or "burn out".

Assembly No retort stands or clamps are required. The 2½-in. diameter ball joint gives a strainless set-up. Outlet cap on boiler for quick periodical drain-off of sediment. The still may be installed on a shelf or platform about 1 ft. above bench level near a sink and enclosed in a transparent plastic cover to keep out dust.

Heat-resisting glass. Interchangeable ground glass joints.

FOOD ANALYSIS

60 secs or 60 minutes

The choice is yours

Today Atomic Absorption Spectroscopy enables the analysis for trace elements in foodstuffs to be performed with unprecedented ease. This technique brings a completely new dimension to this field of analysis.

For example, the determination of arsenic by the Gutzeit method is sensitive but time consuming, the final colour development alone taking up to 60 minutes. By measuring directly Perkin-Elmer's atomic absorption spectrophotometers and accessories reduce this to 60 seconds.

If your problem is arsenic analyses in foodstuffs, Perkin-Elmer's new Electrodeless Discharge Lamps (EDL's) offer the best sensitivity and detection limits available. Compared with the equivalent hollow cathode lamps, the arsenic EDL gives almost twice the sensitivity, ten times the brightness and achieves at least a fivefold improvement in detection limits (Fig. 1). When used with the H.G.A. Graphite Furnace the EDL is capable of analysing 0.01 $\mu\text{g/ml}$ of arsenic in a sample of 20 μl . This detection limit is better than 0.2 p.p.b. in a 100 μl sample. Please write today for further information on how Atomic Absorption and EDL's can help solve your food analysis problem.

new titles

The Series

The Wykeham Science Series has already acquired an enviable reputation around the secondary/tertiary borders. . . Suitable for sixth-form or undergraduate background reading, or as texts in universities and colleges of education, the books provide some good solid meat.
—Eric Deeson, *Education and Training*

26 The Senses of Animals

E. T. BURTT
Explains the senses of animals by analysing their behaviour, the electrical responses of sensory nerves and the structure of sense organs. 0 85109 370 1 paper about £2.00 net available Spring 1974

27 Temperature Regulation

S. A. RICHARDS
The physiology of body temperature is here presented in the style of an introductory monograph.
0 85109 360 2 paper £2.00 net
0 85109 390 6 cloth £2.75 net
1973

28 Chemical Engineering in Practice

G. NONHEBEL
A review of the work with which engineers are concerned in the chemical industry and in many other large industries. Technology, costs and management are covered and illustrated by case histories. The work brings alive the application of several sciences in industry.
0 85109 350 7 paper £2.25 net
0 85109 380 9 cloth £3.00 net
1973

29 An Introduction to Electrochemical Science

J. O'M. BOCKRIS, N. BONCIOCAT and F. GUTMANN
A modern introduction to electrochemistry which explains its relevance to many aspects of twentieth-century technology, and shows the promise that it may hold for pollution-free and abundant energy supplies in the future.
0 85109 410 4 paper £2.00 net
0 85109 420 1 cloth £2.75 net

30 Vertebrate Hard Tissues

L. B. HALSTED
Vertebrate hard tissues, from bones and teeth to horn and eggshells, are traced through their different levels of organisation from molecular and cellular to the tissue and organ systems.
0 85109 430 9 paper about £2.00 net available Spring 1974

A complete catalogue of the Wykeham Science and Technology Series is available on request from the Publishers.

**The Series is distributed in the UK, Europe, Africa and the Middle East
by Chapman & Hall Ltd, North Way, Andover, Hampshire SP10 5BE**

WYKEHAM PUBLICATIONS (London) LTD, 10-14 Macklin Street, London WC2B 5NF

Guide to authors

Nature accepts three types of communications:

- Articles are up to 3,000 words in length with at most six figures and may either be reports of major research developments in a subject or broader reviews of progress.

- Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four figures.

- 'Matters Arising' permits occasional short discussion of papers that have previously appeared in *Nature*. A limit of 350 words is placed on contributions in this category.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible. $\exp(a)$ is preferred to e^a if 'a' is more than one character. Articles should be accompanied by an abstract of not more than fifty words, and the abstract should list the main conclusions that are drawn.

References are indicated by superscripts in the text. The style may be gleaned from any contemporary *Nature* with the following two changes:

(i) If it is necessary to refer to several references by the same author at once, only one reference number need be given.

(ii) The last page as well as the first of any reference should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963-65). 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript. All artwork should be marked with the author's name. Line drawings should preferably be in Indian ink on heavy cartridge paper, although other materials are acceptable; thin, shiny, folded, torn or heavily handled material should be avoided. Matt rather than glossy photographs are preferred. Figures are usually reduced to one column width. The originals should be about twice their final size. Figures, particularly maps, should contain nothing but essential material. It is preferred that the original be unlabelled, but with a copy containing lettering. Labelling on photographs should if possible be avoided entirely. The artwork of published papers can only be returned if a self-addressed envelope is enclosed.

A fuller guide appeared in *Nature* (246, 238; 1973).

Proceedings of the Fourth Lunar Science Conference

Executive Editor **W.A. Gose**
Lunar Science Institute, Houston, USA

This is a three volume set giving the proceedings of the fourth lunar science conference held in Houston in March 1973. It contains full details of much previously unpublished work on the recently completed Apollo programme and is a compendium of the scientific achievements accomplished.

Volume 1: Mineralogy and Petrology

Volume 2: Chemical and Isotope Analysis. Organic Chemistry.

Volume 3: Physical Properties

Available as a three volume set only.

£40.00 (3 volume set)

3,300 pages

April 1974

The Interaction of Gases with Solid Surfaces

W.A. Steele
Professor of Chemistry, Pennsylvania State University

Contents: Introduction; Gas-solid potential energy; Thermodynamics and statistical thermodynamics; Monolayer adsorption; Multilayer adsorption; Molecular beam scattering from surfaces.

£8.00 hard cover

356 pages

April 1974

Phase Transitions 1973

Proceedings of the conference on Phase Transitions and their Applications in Materials Science held at University Park, Pennsylvania May 1973.

Editors **H.K. Henisch and R. Roy**
Materials Research Laboratory, Pennsylvania State University

Partial Contents: Applications of phase transitions in materials science, J.B. GOODENOUGH; Phase transitions in liquid crystals, J. ADAMS; Optical studies on the high pressure phase transformations in silver iodide single crystals, K. VEDAM, J. L. KIRK and S. K. SURI; Theory of semiconductor phase diagrams with applications, J. A. VAN VECHTEN; What good are soft modes?, P. A. FLEURY; Phase transitions in Mossbauer spectroscopy, G. K. WERTHEIM.

£9.80 hard cover

300 pages

April 1974

An Introduction to Spectroscopic Methods for the Identification of Organic Compounds

Edited by **F. Scheinmann**
Senior Lecturer, Department of Chemistry, University of Salford

Volume 2

Contents: An introduction to mass spectrometry; Mass spectrometry seminar problems and answers; An introduction to ultraviolet spectroscopy with problems; Answers to problems in ultraviolet spectroscopy; An introduction to electron spin resonance spectroscopy; Electron spin resonance spectroscopy seminar problems and answers; Some recent developments in nuclear magnetic resonance spectroscopy; The elucidation of structural formulae of organic compounds by application of a combination of spectral methods; Seminar problems and answers in the identification of organic compounds using a combination of spectral methods; Documentation of molecular spectra.

£4.75 hard cover

368 pages

April 1974

£2.85 flexi cover

High speed maths

How many times a day do you use an adding machine, slide rule or scribble calculations on paper? It's a slow old business. Slows down business too.

What you need are high speed fingertip maths as found in the new Tektronix 21 and 31 scientific programmable calculators.

Tektronix-calculator answers are more than instant! They are ready and waiting! Built into the calculator's mathematical logic. Even before you tap your problem in!

Easy-to-understand data feed-in keys labelled with familiar maths symbols and plain everyday English make these calculators amazingly easy to use. Fingertip operation of a data key is a complete mathematical function in key stroke form. It's that simple.

But don't be fooled by the deceptive simplicity of these calculators. Each packs calculating power so great, they solve problems formerly 'computer only.' And at far less cost! What's more the 21 and 31 don't

from your simple key-English programming. Use the 21 and 31 for high speed complex-problem answers to different input variables. Save yourself valuable analytical thinking time. Decision-make with confidence.

With the silent thermal alphanumeric printer, the 31 will 'talk' to you. Give hard copy answers and instant programme advice. Tell you the how, where and what of data entry. Debug, edit and label programmes.

And talking about labels Tektronix is

a relatively new name in calculators. But we've been in electronics for 25 years. We're international precision electronic measurement specialists... with some of the best scientific minds in the world. So it was natural we conceived the 31... at *£1449 one of the most powerful problem-solving-per-£ calculators on the market... followed closely by its smaller brother the 21 at *£940.

Take a calculated step—fill in the coupon, or telephone for full details, and a demonstration now.

Please send details and arrange a demonstration

ROTARY TUMBLER

a new
rotating mixing machine
from
Luckham Ltd

A vertical rotation mixing machine, designed to mix fluids by a tumbling action around a horizontal axis and suitable for use in incubators or hot rooms, as well as at room temperature. The machine accommodates a wide range of stoppered glass test tubes in interchangeable fittings firmly retaining the stoppers.

Mixing is effected by continual inversion of the containers at speeds continuously variable between 10 and 100 r.p.m., enabling the operator to select the optimum mixing action to suit individual requirements. The degree of control is such that the machine is equally suitable for

emulsifying and avoiding, or at least minimising, emulsion formation for such techniques as solvent extraction, whilst maintaining efficient mixing, even with considerable differences in relative densities of fluids.

Since mixing action depends largely on the difference in density of the phases in solvent extraction it is possible to mix efficiently with no air space in the container, any tendency to emulsion formation being reduced as the air space is reduced and correspondingly increased as the air space is increased.

3uv lasers

265-350nm

TUNABLE DYE LASER from Electro-Photonics offers a choice of output from 265nm to about 350nm. This is obtained by frequency doubling the output from a flash lamp pumped dye laser giving a visible output in the TEM_{00} mode of a few mJ with a pulse width of approximately 350ns.

325nm

HELIUM-CADMIUM LASER from Liconix can give over 5mW in the UV. Three models are available giving output at TEM_{00} of 1.0mW, 2.5mW and 5mW. These lasers can be fitted with an interchangeable set of mirrors to give outputs up to 18mW at 441.6nm.

337nm

NITROGEN sealed gas laser from Laser Energy can be pulsed up to 100Hz to give average powers of 20mW. Each pulse has an energy of 200μJ with a pulse width of about 10ns. This system can be used to pump the Laser Energy dye laser giving a tunable output between 370 to 650nm.

We sell many other lasers and laser accessories. See us at **ELECTRO-OPTICS '74** STAND NO. 1002/4.

POLYMER CHEMISTRY

By Professor **B. Vollmert**,
Polymer Institute, University of Karlsruhe, Germany
Translated from the German by E. H. Immergut,
New York
With 630 figures. XV, 652 pages. 1973
Cloth DM 72,—; US \$27.80
ISBN 3-540-05631-9

Prices are subject to change without notice

This book gives a comprehensive coverage of the synthesis of polymers and their reactions, structure, and properties. The treatment of the reactions used in the preparation of macromolecules and in their transformation into cross-linked materials is particularly detailed and complete. The book also gives an up-to-date presentation of other important topics, such as enzymatic and protein synthesis, solution properties of macromolecules, polymer crystallization, and properties of polymers in the solid state.

The content and presentation of Professor Vollmert's book is more encompassing than most existing treatises, and its numerous figures and tables convey a wealth of data, never, however, at the expense of intellectual clarity or educational value.

The presentation is mainly on a fundamental and general level and yet the reader—student or professional—is gradually and almost casually introduced to all important natural and synthetic polymers. Complicated phenomena are explained with the aid of the simplest available examples and models in order to ensure complete understanding. However, the reader is also encouraged to think for himself and even to criticize the author's point of view.

All of the chapters have been revised and enlarged from the German edition, and many of the sections are entirely new.

Contents

Introduction. — Structural Principles. — Synthesis and Reactions of Macromolecular Compounds. — The Properties of the Individual Macromolecule. — States of Macromolecular Aggregation.

Guide to authors

Nature accepts three types of communications:

- Articles are up to 3,000 words in length with at most six figures and may either be reports of major research developments in a subject or broader reviews of progress.

- Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four figures.

- 'Matters Arising' permits occasional short discussion of papers that have previously appeared in *Nature*. A limit of 350 words is placed on contributions in this category.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible. $\exp(a)$ is preferred to e^a if 'a' is more than one character. Articles should be accompanied by an abstract of not more than fifty words, and the abstract should list the main conclusions that are drawn.

References are indicated by superscripts in the text. The style may be gleaned from any contemporary *Nature* with the following two changes:

(i) If it is necessary to refer to several references by the same author at once, only one reference number need be given.

(ii) The last page as well as the first of any reference should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963-65). 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript. All artwork should be marked with the author's name. Line drawings should preferably be in Indian ink on heavy cartridge paper, although other materials are acceptable; thin, shiny, folded, torn or heavily handled material should be avoided. Matt rather than glossy photographs are preferred. Figures are usually reduced to one column width. The originals should be about twice their final size. Figures, particularly maps, should contain nothing but essential material. It is preferred that the original be unlabelled, but with a copy containing lettering. Labelling on photographs should if possible be avoided entirely. The artwork of published papers can only be returned if a self-addressed envelope is enclosed.

A fuller guide appeared in *Nature* (246, 238; 1973).

A new d.c. Microvoltmeter

The TF 2655 is a high-grade, versatile, general-purpose instrument with 18 voltage and 14 current ranges, all with an accuracy of $\pm 2\%$ f.s.d.

Its main features are:

- * push-button selection of ranges and polarity
- * high-input resistance of $10^6 \Omega$ to $10^{11} \Omega$
- * low constant voltage drop of 10mV on all current ranges
- * off-set zero
- * large, 9.5cm, clear-reading, mirror scale
- * input overload protection $\pm 100V$ up to 1V range, and $\pm 1,200V$ on remainder

Ranges: $3 \mu V$ to 1,000V f.s.d. in 3/10 sequence (18 ranges)

300pA to 1mA f.s.d. in 3/10 sequence (14 ranges)

Price: £150.

Made in Poland.

Full details from:

MARCONI INSTRUMENTS LTD.
Longacres, St. Albans, Herts, AL4 0JN,
Telephone: St. Albans 59292. Telex: 23350.
A GEC - Marconi Electronics Company.

Diamond or Abrasive Wheel Cut-off Machine **MODEL GSP 210**

Cuts Rock, Refractories Ceramics Glass or Metals

A simple to operate machine with application in all fields where hard materials are cut.

The vice unit will grip either regular or irregular specimens, and has a detachable vee jaw for clamping rods, cores or tubes.

Coolant pipes on both sides of the cutting wheel supply ample cooling during cutting. The machine can be supplied with a settling tank and pump unit if required.

Additional equipment—cross slide with $2\frac{1}{2}$ " movement.

High speed vibration free taper roller bearing spindle.
Standard Cutting Wheels, 8" diameter \times 1/16" or 1 mm wide.
Area of cut 5" \times 2 $\frac{1}{2}$ "—Drive flat nylon belt.—
Dimensions—length 30", width 28", height 16". Wt. 1 cwt.

Staff changes

THIS is the last issue for which Edward Phillips is the Physical Sciences Editor. He has been with *Nature* for six years and has built up an enviable reputation as a firm but kindly intermediary between referees and authors. He goes to a new job with the European Commission in Luxembourg.

Roger Woodham becomes Physical Sciences Editor. He did a PhD in cosmic-ray physics and has most recently been Production Editor.

Peter Newmark joins *Nature's* staff as Biological Sciences Editor. He has been a biochemist at St Bartholomew's Hospital, London and is author of a Penguin book, *Out of your mind?*

Guide to authors

Nature accepts three types of communications:

- Articles are up to 3,000 words in length with at most six figures and may either be reports of major research developments in a subject or broader reviews of progress.

- Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four figures.

- 'Matters Arising' permits occasional short discussion of papers that have previously appeared in *Nature*. A limit of 350 words is placed on contributions in this category.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible. *exp (a)* is preferred to *e^a* if 'a' is more than one character. Articles should be accompanied by an abstract of not more than fifty words, and the abstract should list the main conclusions that are drawn.

References are indicated by superscripts in the text. The style may be gleaned from any contemporary *Nature* with the following two changes:

(i) If it is necessary to refer to several references by the same author at once, only one reference number need be given.

(ii) The last page as well as the first of any reference should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963–65). 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript. All artwork should be marked with the author's name. Line drawings should preferably be in Indian ink on heavy cartridge paper, although other materials are acceptable; thin, shiny, folded, torn or heavily handled material should be avoided. Matt rather than glossy photographs are preferred. Figures are usually reduced to one column width. The originals should be about twice their final size. Figures, particularly maps, should contain nothing but essential material. It is preferred that the original be unlabelled, but with a copy containing lettering. Labelling on photographs should if possible be avoided entirely. The artwork of published papers can only be returned if a self-addressed envelope is enclosed.

A fuller guide appeared in *Nature* (246, 238; 1973).

Guide to authors

Nature accepts three types of communications:

- Articles are up to 3,000 words in length with at most six figures and may either be reports of major research developments in a subject or broader reviews of progress.

- Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words; at most they have three or four figures.

- 'Matters Arising' permits occasional short discussion of papers that have previously appeared in *Nature*. A limit of 350 words is placed on contributions in this category.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible. $\exp(a)$ is preferred to e^a if 'a' is more than one character. Articles should be accompanied by an abstract of not more than fifty words, and the abstract should list the main conclusions that are drawn.

References are indicated by superscripts in the text. The style may be gleaned from any contemporary *Nature* with the following two changes:

(i) If it is necessary to refer to several references by the same author at once, only one reference number need be given.

(ii) The last page as well as the first of any reference should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed. (Butterworth, 1963-65). 'Personal communication' and 'unpublished work' should be incorporated in the text.

Artwork should be sent with the manuscript. All artwork should be marked with the author's name. Line drawings should preferably be in Indian ink on heavy cartridge paper, although other materials are acceptable; thin, shiny, folded, torn or heavily handled material should be avoided. Matt rather than glossy photographs are preferred. Figures are usually reduced to one column width. The originals should be about twice their final size. Figures, particularly maps, should contain nothing but essential material. It is preferred that the original be unlabelled, but with a copy containing lettering. Labelling on photographs should if possible be avoided entirely. The artwork of published papers can only be returned if a self-addressed envelope is enclosed.

A fuller guide appeared in *Nature*, (246, 238; 1973).

Reagents for the unambiguous assay of REVERSE TRANSCRIPTASE

Reverse transcriptase can be distinguished from cellular DNA polymerases by using appropriate combinations of the following complexes as template primers:

- POLYRIBOADENYLIC ACID •
OLIGODEOXYTHYMIDYLIC ACID
- POLYDEOXYADENYLIC ACID •
OLIGODEOXYTHYMIDYLIC ACID
- POLYRIBOCYTIDYLIC ACID •
OLIGODEOXYGUANYLIC ACID
- POLYDEOXYCYTIDYLIC ACID •
OLIGODEOXYGUANYLIC ACID

The most important ones currently being used extensively in screening programs for reverse transcriptase are listed below:

	5 Units	25 Units
7855 POLY(rA)•d(pT) ₁₀	\$30.00	\$125.00
7850 POLY(dA)•d(pT) ₁₀	38.00	150.00
7878 POLY(rA)•d(pT) ₁₂₋₁₈	30.00	125.00
7868 POLY(dA)•d(pT) ₁₂₋₁₈	38.00	150.00
7944 POLY(rC)•d(pG) ₁₂₋₁₈	40.00	160.00
7943 POLY(dC)•d(pG) ₁₂₋₁₈	50.00	200.00

For an example of assay conditions used for the determination of cellular DNA polymerases and reverse transcriptase see: *Science*, **183**, 867 - 869 (1974).

A complete series of synthetic RNA and DNA polynucleotides and oligonucleotides is available from P-L Biochemicals. See our Catalog 103 for the total listing.

Differentiation

Differentiation, published bi-monthly, provides the opportunity for interdisciplinary communication. This journal offers up to date information and synthetic views of a problem underlining the whole biological phenomenon - differentiation. It aims to cover the following areas of study: embryonic differentiation, normal cell growth and division, carcinogenesis and the cancer problem as an aspect of cell differentiation, inter-tissue reactions in vivo and in vitro, genetic mosaicism, nucleo-cytoplasmic interactions, nuclear transplants, cell hybridization, evolutionary biology, membrane controls of the cell, plant evolution and differentiation, immunological events relevant to differentiation.

Recent papers include:

Degree of differentiation in non-proliferating cells of mammary carcinoma, C. V. Wyllie, P. K. Nakane and G. B. Pierce. **DNA synthesis and the production of antibodies by lymphoid tissues**, G. Harris. **The principle of sequential dependence in cellular differentiation**, P. A. Riley. Edited by: Dimitri Viza. Faculté de Médecine Pitié Salpêtrière, Paris.

Annual subscription £20 (£22.00 U.S.A. and Canada).

Prices applicable only to orders started before 31st December, 1974. Payment may be made in any currency at the current exchange rate. Orders must be accompanied by remittance. Cheques should be made payable to: Macmillan Journals Limited, Subscription Department, Brunel Road, Basingstoke, Hampshire RG21 2XS, England.

MARINE POLLUTION BULLETIN

Marine Pollution Bulletin is published monthly and sets out to cover all aspects of the fight for life of lakes, estuaries, seas and oceans. It includes news, comment, reviews and research reports not only on the threats of noxious substances to marine life but also on the management and productivity of the marine environment in general. It publishes accounts of new and proposed research programmes as well as the results of those in progress.

Recent research reports include:

Distribution of Caesium-137 in British Coastal Waters, D. F. Jefferies, A. Preston and A. K. Steele. **Export of Lead from Salt Marshes**, M. Banus, I. Valiela and J. M. Teal. **International Scope of Marine Pollution Damage**, D. P. Tihansky. **Effects of Red Mud on Marine Animals**, R. A. A. Blackman and K. N. Wilson. **Pollution Problem of the Golden Horn**, M. Karpuzcu.

Annual Subscription £6.50 (£7.50 USA and Canada).

Prices applicable only to orders starting before 31 December 1974. Payment may be made in any currency at the current exchange rate. Cheques should be made payable to Macmillan Journals Ltd., Subscription Department, Brunel Road, Basingstoke, Hampshire RG21 2XS, England.

The politics of biomedical research

FOR the past eighteen months, the Nixon Administration and the biomedical research community in the United States have been engaged in a verbal battle over the management and funding of medical research. Some fundamental principles are at stake, and some deep divisions—which have resulted in the dismissal or resignation of senior officials of the National Institutes of Health—have occurred. It is important, for the health of the biomedical research effort in general, and for the future of NIH in particular, that the differences of opinion should be resolved. But how?

The nub of the dispute is this. For years, the National Institutes of Health has enjoyed considerable autonomy. It has largely been sheltered from policy decisions imposed from the White House, or from the headquarters of its parent department, the Department of Health, Education and Welfare. It has established a well-deserved international reputation, and its efforts have contributed to advances in the treatment of numerous diseases. But its budget has grown to the point at which the Office of Management and Budget is understandably asking what return the Administration is getting on its investment in biomedical research. Policy decisions vitally affecting the day-to-day operations of NIH are increasingly being made in OMB and HEW, and NIH officials and scientists therefore complain of a loss of autonomy.

Superimposed on this drift toward increased budgetary control from outside NIH is a move toward what NIH scientists refer to as 'politicalisation of research'. In the past two years, Congress has passed two bills designed to increase funding for research on cancer and diseases of the heart and lungs. The result has been that the National Cancer Institute and the National Heart and Lung Institute have both enjoyed large funding increases, while other institutes have either had their budgets cut or held constant. Moreover, an increasing proportion of the funds channelled through NIH are spent on contracts rather than the traditional grants. Contracts provide a mechanism by which research projects can be more tightly controlled. NIH scientists argue that these trends have unbalanced the overall biomedical research programme, and have taken money away from the individual university scientist—the man who has traditionally provided most of the main breakthroughs in research.

In a recent letter to the *Washington Post*, Dr Charles C. Edwards, Assistant Secretary for Health in the Department of Health, Education and Welfare, argued that NIH can no longer expect to have the autonomy it once enjoyed. Research money should be targeted on problems whose solution would have the greatest benefit for society, he argued, and the Administration has every right to expect a return on its investment.

The scientists replied that while the amount of money to be devoted to biomedical research is indeed a political question, the manner in which it is spent should be decided entirely on scientific grounds.

Both viewpoints are eminently reasonable, but can they be reconciled? Last week, Dr Edwards spoke to scientists at NIH, and according to reports, he reassured them that scientists, not politicians, would always have the final say on how research funds should be spent. Although much of his talk offered such reassurances, scientists who attended came away unconvinced that their case has really been accepted by the Administration. And their fears were fueled by the fact that the Administration's budget for 1975 carries through the trend of increasing expenditures on cancer research and heart and lung research, while holding other areas constant. Such distrust indicates the need for new planning mechanisms to be introduced for biomedical research.

Last week, Senator Edward Kennedy offered at least a step in this direction (see page 4). He has suggested that a three-member council should be set up to report directly to President Nixon on the overall balance and content of the biomedical research programme. Such a body would at least provide some insulation between NIH and the rest of the Administration. At all costs, however, the danger that it would simply turn into an outlet for the scientists' complaints, and thus generate more heat than light, must be avoided. Whether that will happen will depend to a large extent on who is appointed.

100 years ago

THE young King of Siam having come of age on October 10 last, great feasts were given to his subjects at Bangkok, the chief town of his dominion. Amongst other attractions was the ascent of a small mounted balloon, which had been constructed in Paris and had arrived by steam a few days previously. Liberal offers were made to procure an aeronaut, but were of no avail, nobody amongst the Siamese presuming to ascend. Consequently his Majesty ordered a slave, selected from amongst the less heavy of his household, to be sent up in the car. In order to encourage the poor aeronaut, so frightened for his life, he was promised to be rewarded with his enfranchisement. The ascent took place and elicited much enthusiasm from the bystanders; but, unhappily, nothing was heard from the poor fellow or of the craft.

From *Nature*, 9, 350, March 5, 1874.

Protest about emigration from the Soviet Union

Vera Rich, London

THE right of the Jewish intelligentsia to emigrate from the Soviet Union to Israel has been raised once again by the fast, in Moscow, of David Azbel, a professor of chemistry, Vitalii Rubin, an eminent Sinologist, and Vladimir Galatskii, a talented but little known artist. In a statement issued on the first day of their protest, the three participants declared:

"We begin today a hunger strike, taking a step befitting political prisoners. We consider ourselves as such even though we live in Moscow in our flats and with our families. One can deprive a human being of his liberty even without arresting him. The case then, is of arrest without investigation, without a trial and without a date for release".

Since October 1971 when the Soviet restrictions of Jewish emigration to Israel were relaxed insofar as total numbers were concerned, it has become increasingly clear that the new policy was not to be applied on a basis of equality. According to a law of 1942, all persons wishing to emigrate from the Soviet Union are obliged to pay 400 roubles for an exit visa, plus 500 roubles for renouncing their Soviet citizenship—900 roubles in all (£450). In addition to this, however, a new principle was introduced on August 3, 1972—that all persons with higher education wishing to emigrate should first refund to the state the cost of that education.

In a press statement made through the Novosti agency (December 28, 1972) Deputy Minister of the Interior Boris T. Shumilin explained this policy in terms of economic pragmatism with a touch of socialist solidarity. "The Soviet Union", he said, "has no intention of acting as a philanthropist towards persons on whose education the state has spent considerable sums, or towards those capitalist states to which these persons are emigrating".

For this reason the repayment of fees is not demanded from those departing for socialist countries or those which have "taken the road to independent development", since special agreements exist between the Soviet Union and

these countries concerning the repayment of fees. Persons of retirement age and invalids are, he said, exempt from all repayments, and rebates are given in accordance with the length of time worked (for example, 75% rebate for a man with a working record of 25 years or a woman with a working record of 20 years).

One would expect that since the state demands such high 'transfer fees' for its valuable personnel (a record figure of 23,000 roubles paid by an unnamed Jewish composer was reported in February, 1973), it would use these human 'assets' in the best interests of the Soviet economy. This, however, is not the case. Although it is not illegal to apply for

David Azbel

emigration to Israel, clearly those who do so are dissatisfied with the Soviet regime. And dissatisfaction with the regime is viewed by the authorities as dissent and, in many cases, as mental illness.

Thus one has the anomaly that a scholar such as philologist Vitalii Shevuroshkin, refused an exit visa on the grounds that his services were "indispensable" to the Soviet Academy of Sciences, was shortly afterwards dismissed from his post. One presumes that no adequate replacement can be found!

Since March 1973, when the enforcement of this 'diploma tax' threatened to jeopardise Soviet-United States trade

agreements, it would seem that the repayment of higher education fees has no longer been enforced. But the journalist Victor Louis, who seems to have a special insight into the workings of the KGB, informed the Israeli newspaper *Yediot Aharonot*, that "although it had not been abolished, the tax would not in future be demanded". Inverting the proposition, this means that although for those intellectuals fortunate enough to be allowed to leave as a sop to opinion abroad (five left with much publicity at the time of the said trade talks), it remains unrevoked and could be reimposed at any time.

Instead of the diploma tax, recent policy has been one of ever increasing harassment of the would-be emigrant. He is seen as a dissenter and dismissal from his post is the least that he can expect. In the case of the electrochemist Dr Venyamin Levich, his own dismissal was followed by the exiling of his astrophysicist son to Siberia (in spite of suspected cancer of the stomach) and a curious attempt to impose the "academic oblivion" of Stalinist days.

The distribution of foreign scientific journals has been handled by the Institute of Information, which photocopies the journals and then distributes these copies to libraries and subscribers. This means that 'undesirable' material can be removed at this stage and, in order to cover up the omission, replaced by innocuous material such as book reviews from other issues.

In reproducing the *Journal of the Chemical Society*, No. 8, 1973, (which makes reference to Levich's work) the older blanking-out type of censorship was, however, adopted, so that references to the "Levich-Dogonadze" theory become references to the "... Dogonadze" theory throughout the Soviet version, except in one case where Levich's name remains by an apparent oversight (see Fig. 2).

Professor David Azbel, one of the three participants of the present 'hunger strike' was 61 years old when he applied, in May 1972, to emigrate to Israel and therefore, according to the Shumilin statement, should have qualified for emigration without payment of the diploma tax. His life history up to this time reads like a synopsis of some Solzhenitsyn novel. Orphaned at the age of nine—he was forced to watch his mother hanged during a White pogrom in the Civil War—he made his way as

A number of theories of oxidation-reduction and electrochemical electron exchange reactions have appeared. Common to several of these theories is a particular approximation method embodied in the use of the dielectric continuum representation of the electrically polarizable nature of the solvent system surrounding the reactants and products: the electron donor and acceptor species. In addition, one theory is fundamentally quantum mechanical; this theory has been developed to a considerable extent by Dogonadze and their associates.¹⁻⁴ The Dogonadze solution electron transfer theory¹ resembles the solid state polaron theory.⁵ Further, the Dogonadze theory owes much to the Born-Oppenheimer adiabatic separation of the transfer electron dynamics from environmental motions for its progress from the conceptual model, with its associated Hamiltonian operator, to the expression for the rate constant. The advantage in the application of the Born-

one of the numberless 'waifs of the Revolution' from his native Ukraine to Moscow, where distant relatives gave him a home. He graduated in 1935, just in time to be arrested in the first wave of Stalin purges. He was released in 1951 and was 'exiled' back to Ukraine, where he worked as an engineer until he was dismissed from his post in the wave of anti-Semitism at the time of the alleged "Doctors' Plot" against the life of Stalin.

After Stalin's death, he was 'rehabilitated', allowed to return to Moscow, where he completed his postgraduate studies, becoming a doctor of technical sciences in 1960 and a professor in 1961. In 1968 he became head of the Institute of Chemical Spirits and Organic Products in Moscow. During this time he published some 60 scientific papers, dealing with mass transfer, bubbling regimes and the kinetics of biochemical processes.

In May 1972, at the age of 61 (and therefore exempt from any 'diploma tax' according to Shumilin's pronouncements), he applied to emigrate with his wife and child to Israel. He was immediately dismissed from his post and the long harassment started. In December 1972, he was arrested with other Soviet Jews following a hunger strike outside the Central Telegraphic Office in Moscow and was sentenced to 15 days' imprisonment for "holliganism". In October 1973 he was reported arrested in Leningrad in a general round-up of leading Jews at the time of the Yom Kippur War. A few days later, he is said to have been in hiding in his Moscow flat, under constant surveillance by the KGB and afraid to leave, even to buy food, lest he be arrested. Although these last reports seem somewhat contradictory, the general impression of harassment is unmistakable.

So, with his friends Rubin and Galatskii, he now considers himself a "political prisoner", although as yet all three live in Moscow in their own flats and with their families. Compelled in 'the interests of the state' to remain in the Soviet Union at a time when it is ready to expel such 'undesirables' as Solzhenitsyn, they are undertaking his hunger strike to draw attention to the

anomalous position of the Soviet Jewish intelligentsia. Although the official propaganda sources stress that "tens of thousands" of Russian Jews are permitted to leave, these figures, say Azbel and his companions, only mask the 'human drama' of the Jewish intelligentsia, who "From the moment we applied for exit visas . . . have been victims of endless harassment, our dignity as human beings often degraded. We have had to face officials who could torture us at will. Our application to higher officials proving our just causes were answered by lies and mockery. Our protests were answered by repression".

New riot control agent for US Army

Colin Norman, Washington

A CONTROVERSIAL new riot control agent, which was developed in Britain, has been approved for use by the United States Army. Called CR, it is a highly potent irritant to the eyes and skin, and it is likely to be at least a partial replacement for CS, the riot control agent widely used in Vietnam. The first public indication of the approval of CR for use by US forces was contained in a letter sent last week by Dr Malcolm Currie, the director of research and development in the Department of Defense, to Wayne Owens, a Democratic Congressman from Utah.

Developed at Britain's Chemical Defense Establishment at Porton Down, CR (its chemical name is dibenzoxazepine), is considered by both the British and US governments to have some advantages over CS as a riot control agent, chief of which is that it can be sprayed rather than disseminated by a smoke bomb.

CS is relatively indiscriminate in its effects—when used in a wind, it tends to blow away from the target area, and even to blow back into the faces of the troops using it. There have also been reports that rioters can develop a tolerance for its irritant effects. CR, however, can be used as a liquid suspension in propylene glycol, which means that it can be sprayed directly at the target.

The agent was issued to British troops in November last year, amid considerable criticism because the British government had released only scant information about the toxicity of the agent. No further information has yet been issued in the United States, although the most comprehensive tests were carried out at the Edgewood Arsenal in Maryland. According to Currie's letter, the US government is precluded from releasing reports of those tests because the Department of Defense "is bound by the terms of the standardization agreements not to release information derived from the property of foreign governments". He added, however, that "the UK has now embarked on an active program to present information on CR in the scientific literature. We anticipate, therefore, early release of some technical publications concerning our investigations".

The most comprehensive data so far published on CR were contained in an article in an obscure British magazine, *Medicine, Science and the Law* (October, 1973), which was written by senior officials from Porton Down. The paper described tests on 150 male volunteers, and it described the effects of CR as being very sharp and painful, and they lasted for about 20 minutes. The agent also causes the victim to shut his eyes tightly.

As for toxicity, such information as there was in the article suggests that the toxicity of the agent is low, but it was entirely inadequate to gauge the long-term effects. The key data are contained in the reports of the Edgewood Arsenal studies, and until those are released, no adequate scientific judgement of the risks associated with exposure to CR can be made. It should be noted that the Himsworth Committee, which was set up by the British government to study the use of CS, strongly recommended that all new riot control agents should be thoroughly tested and the results opened up to public debate before they are issued to the armed forces. This did not happen with CR in Britain, and the United States government has quietly followed Britain's bad example.

Should pharmaceuticals be left alone?

Roger Woodham

WHAT precisely is the Labour Party's policy for the British pharmaceutical industry? The Association of the British Pharmaceutical Industry (ABPI), for one, is not waiting any longer to find out and has published a hard-hitting riposte to that part of the Labour Party Election Manifesto that deals with future

public ownership in the industry. Predictably the association's conclusion is "leave well alone".

The manifesto devotes all too little space to spelling out just what the party has in mind. A public holding, it says, is necessary in certain industries to allow control of prices, stimulation of investment, encouragement of exports . . . There are evidently several choices.

- Nationalisation of some or all British companies manufacturing pharmaceutical products (including the British ends of multinational companies in the extreme case) .

- The setting up of a state holding company which would buy a controlling share in specified companies.

- The floating of a new company in competition with the rest.

The permutations are almost endless. Perhaps the Labour Party has in mind simply hiving off to the state certain parts of companies (declining, for example, to involve the nation in the soft drinks or cosmetics markets). In any event the 'big six'—Glaxo, Beecham, Fisons, ICI, Wellcome and Boots—are likely to feel a cold wind if the public ownership policy is ever implemented.

The ABPI argues its case against public ownership by posing and answering 13 questions. Is there any evidence, the association asks for example, that nationalisation can benefit the health of the public and the national economy? Its answer is "no", and that nationalisation would "stifle research success and reduce the industry's £220 million plus a year export record . . ." Certainly the ABPI has a point about exports, for if foreign-based companies ceased to operate in Britain about half that export potential could be lost.

This is not such an unlikely state of affairs, for any government could, if it wanted, decimate the British pharmaceutical industry in its present form by taking over one company. (Glaxo, which has a turnover of about £200 million, is a possibility for it has the added attraction of having two factories in development areas, at Alzerston in Lancashire and at Montrose in Scotland.) Given the manufacturing base the government could then invoke clauses in the 1948 Patent Act and the 1968 National Health Service and Public Health Act, which allow it to abrogate drug patents for the benefit of the public sector. Few foreign companies would stay in Britain in these circumstances. And, of course, a government buying even a part share in a foreign-based company would simply be buying bricks and mortar and a disillusional staff; no new ideas would ever again reach it from its parent.

What of research? The ABPI document boasts that the pharmaceutical industry plans to double its present

research investment during the next few years and generally expresses approval for the way in which pharmaceutical companies set about things. The objection, however, is that it is hard for a private company to justify to itself research in areas that are not seen to be potentially profitable. Presumably a national pharmaceutical corporation, or whatever, would do much less screening of compound upon compound for signs of biological activity of a desired kind, and concentrate instead on identifying problem diseases and looking, more 'scientifically', for a cure.

There is talk among Labour politicians that the British pharmaceutical research budget according to Labour plans would make the present spending look like peanuts, but there are others who would hardly bother with research at all and would concentrate on manufacturing generic drugs extremely cheaply. The national drugs bill footed by the government might be reduced from 7% of the cost of the National Health Service to 3% or 4% in this way, hardly a handsome return for such an extreme move.

The right balance may well have been struck by Pfizer, whose research effort in Britain was mainly fundamental a few years ago but is now split almost equally between the fundamental and the pragmatic.

Making out a case for the Coalplex

John Wilson

THE National Coal Board (NCB) is asking the government to provide "about £40 million" for research and development as part of a £400 million investment programme. The NCB has already carried out a great deal of fundamental research into new ways of producing energy and raw materials from coal at the Coal Research Establishment, Stoke Orchard, Cheltenham. Now it wants to set up pilot plants to assess the feasibility of its ideas on a larger scale.

Describing the diversity of the work now in progress, Dr J. Gibson, Director of the Stoke Orchard establishment, says that it ranges from the production of carbon fibre to the use of colliery spoil in motorway construction. But he outlines a unifying theme behind much of the research—the creation of a 'Coalplex'. A Coalplex is a single site where several processes for the extraction of energy from coal, usually in the form of electricity or gas, can be linked to the manufacture of other coal products such as metallurgical coke. The processes may be combined in almost any permutation so a Coalplex could provide different coal products if the emphasis on

Kennedy floats a critical plan

Colin Norman, Washington

IN an effort to provide a highly visible channel for independent criticism of the Administration's biomedical research policies, Senator Edward M. Kennedy has proposed that a three-member Presidential panel should be set up to keep an eye on the programmes of the National Institutes of Health (NIH). The proposal stems from the fact that for the past two years, the Administration has favoured the National Cancer Institute and the National Heart and Lung Institute with large budget increases, chiefly at the expense of other areas of biomedical research. Kennedy, backed by a number of influential scientists, believes that this trend is creating considerable unbalance in the overall biomedical research effort.

The panel, which was proposed in a bill Kennedy introduced last week, would be akin to the President's

Cancer Panel, a body which now overseas the national cancer programme. It would consist of three members, one of whom would be the chairman of the cancer panel, and at least two of whom would be "distinguished scientists or physicians". Its brief would be to report directly to the President and Congress on any delays or blockages in the execution of NIH's programmes—a definition sufficiently broad to allow the panel to voice its opinion on most aspects of research policy.

The bill has been sent to Kennedy's Senate Health subcommittee, where it will probably be attached to another bill which proposes some relatively minor changes in the National Cancer Act. Since it is being cosponsored by Senator Jacob Javits, the ranking Republican on the health subcommittee, there is every chance that it will be speedily approved. Meanwhile, a similar bill is being introduced into the House of Representatives by Paul G. Rogers, the chairman of the subcommittee on health of the House Commerce Committee. Again, little opposition is expected there.

the various individual processes were altered.

One part of a Coalplex could be used to supply the raw material (such as 'lean' gas of low calorific value) for several different processes and the by-products of one process could be utilised by another. In this way the overall capital cost of a Coalplex would be reduced and its efficiency increased. Dr Gibson points out that with the old town gas system, only the quantity of the products—gas, tar and coke—could be altered, not their proportion. In a Coalplex, no unwanted materials need be made.

Dr Gibson emphasises, however, that the setting up of a Coalplex represents the culmination of the research effort at Stoke Orchard rather than the core of present plans. It is the building of pilot plants to test the individual processes that is most urgent now, he says.

Perhaps one of the most important of these processes is the fluidised bed combustion of coal (FBC). The coal is burned in a sea of coal ash given the properties of a liquid by the upward passage of air. Low grade coals may be used and indeed coal washings, composed of 50% water, 25% ash and only 25% combustible material, have been successfully burned. This raises the interesting possibility of recycling some coal tips.

The equipment required by an FBC system is cheaper and more reliable than conventional apparatus, says Dr Gibson, and the process is also less harmful to the environment. Being about 10% more efficient than existing generating stations powered by coal, any FBC station would require much less water for cooling. Moreover, by adding limestone to the bed of ash, the amount of sulphur dioxide given off can be substantially reduced. With the growing concern about thermal and atmospheric pollution, Dr Gibson feels that these are important points to consider.

Because FBC is an efficient method of releasing the energy in coal, it could form a base around which a Coalplex might be built. It can also be adapted to the direct gassification of the coal, thus providing a gas from which oil can be produced. But other processes are also needed to extract the various coal products and these, too, require the development of pilot plants.

One way of obtaining coal products is to dissolve the coal in a solvent such as anthracene oil. The solution can then be used in the manufacture of carbon fibre and electrode coke. Dr Gibson claims that this coke is of sufficient quality for use in the arc processes of the steel and aluminium industries. Another extraction process which Dr Gibson would like to see in pilot operation involves the vaporisation of the coal into compressed gases held just above their criti-

cal temperature. When the resulting mixture is drawn off and cooled the coal extract can be precipitated out.

In the long term processes such as these could be the initial steps in the preparation of liquid fuels and chemicals. These might then be processed using the techniques of the petrochemical industry. With its high content of hydrogen, the gas extract is particularly suitable.

The idea of a Coalplex was first proposed by Lord Zuckerman in 1971 and most of the fundamental principles have been known for some time (aviation fuel was made from coal in Germany during the Second World War). But why has the NCB been so slow to exploit this concept? The answer lies in the economics of the operation. Quite simply it was, until very recently, several times cheaper to produce most of these materials from oil. The NCB had been thinking of an economic Coalplex in terms of 10 or 15 years from now. Recent events in the Middle East and a growing shortage of carbon products have changed this outlook. That is why the board wants to take the expensive step out of the laboratory on to the pilot site.

Nevertheless, Dr Gibson is careful to point out that he envisages a situation where coal and oil are complementary to the needs of industry and not in competition. Oil is a natural resource which contains a lot of energy and it would be a shame, he says, if such a fine material were degraded to gas, carbon fibre and other more mundane uses. If coal were used to produce these basic materials, it would relieve oil of a considerable burden.

NASA and Europe look to the planets

Colin Norman, Washington

Discussions have been held between officials of the National Aeronautics and Space Administration and their counterparts in Europe on the possibility of a joint United States-European mission to Jupiter. During a recent visit to five European countries, NASA officials floated the idea of European cooperation with the United States on a project which would involve use of Pioneer-H, the redundant backup spacecraft for NASA's two Jupiter Pioneers. The possibility of a joint mission to the comet Eake in 1980 was also discussed. The European response was "very enthusiastic", and firm proposals are likely to be made by September.

Two chief choices are being discussed. The first would involve a launch in 1978 and Jupiter encounter in 1980 which would take the spacecraft on a

trajectory underneath the planet, to emerge north of the ecliptic plane. After Jupiter encounter, it would then go on towards the Sun, passing over the north solar pole and swinging round the Sun past the south pole. If the mission goes ahead, it would be the first spacecraft to be sent out of the ecliptic.

The second choice would be to launch Pioneer-H in 1980 on a Jupiter orbiter mission. Such a mission would extend the observations of the two Jupiter swingby missions.

Although the costs are not yet clear, the out-of-ecliptic flight would be the cheaper option. At present, Pioneer-H has a set of instruments which duplicates those carried on the Pioneer-10 and 11 swingby missions. An orbiter mission would require the development of retro rockets and some changes in instrumentation, while the Jupiter swingby, followed by the out-of-ecliptic solar flight would only require the addition of a few solar instruments.

The exact mode of cooperation is still being worked out, but as far as the orbiter is concerned, the idea would probably be that the Europeans would provide the retro rockets.

The cost of immunisation

Sally Owen

ABOUT 2,000 children suffering from vaccine damage in Britain are not eligible for compensation because of the terms of reference of the Royal Commission on Compensation and Civil Liability. After a recent report that permanent brain damage followed immunisation against whooping cough in one child in about 5,000, Mr Jack Ashley, a Labour Member of Parliament, has drawn attention to this anomaly in the law and has accused the government of "shattering complacency" in its attitude towards children damaged by vaccines.

A successful campaigner for compensation on behalf of Thalidomide children, Mr Ashley referred to a "veil of obscurity" shrouding the fate of thousands of children and he asked for urgent action to reduce the number of future tragedies. He has also proposed that compensation should be offered to those already severely damaged.

Following Mr Ashley's campaign in the House of Commons, an association formed last year in the interests of children damaged by vaccines has been receiving letters of support from parents.

The Association of Parents for Vaccine-damaged Children feels that Britain should have compensation schemes for the casualties of vaccine administration, as do most European countries. There

are no compulsory immunisation procedures in Britain, whereas they are common in the rest of Europe.

Compensation for damaged children was discussed almost a year ago at a conference held in Monte Carlo on vaccination against communicable diseases. Although there was a strong call for a code of guidelines for vaccine trials, it was pointed out that public concern would jeopardise future trials. Standards of conduct satisfying both scientific integrity and lay opinion would be required.

Another view expressed at the conference was that there is a good case for compulsory immunisation against some illnesses; for instance a child with quadriplegia due to poliomyelitis might be justified in suing his parents for negligence in not having had him immunised against the disease.

The compensation schemes practised in Denmark and Germany are controlled by the authorities, who are responsible for individual claims for damages. This means that if it is suspected that a vaccine is faulty the manufacturer can be sued.

The choice of vaccines used in European countries, including those for compulsory immunisation, differs widely and it is predicted that within the next few years closer agreement will be reached on the pattern of immunisation schedules.

In Britain concern is being expressed about the whooping cough vaccine which was first introduced nationally in 1957. Since then there has been a marked decline in the disease. It is, however, known that some children—there are no reliable figures—have been seriously damaged by the use of the vaccine. In 1972 general medical practitioners were given advice on possible adverse reactions to whooping cough vaccine and certain children were recommended not to receive it.

The Committee on Safety of Medicines was not entirely satisfied with the voluntary reports received on adverse reactions. The reports did, however, identify possible problems with adverse reactions in the various immunisation procedures. In fact neither the committee nor its predecessor, the Committee on Safety of Drugs received reports of direct adverse reactions to whooping cough vaccine.

Whooping cough vaccine is usually given as part of a triple injection for diphtheria, whooping cough and tetanus, or as a quadruple injection in which case poliomyelitis is the additional vaccine. Even though it is usually considered not possible to ascribe any adverse reactions to an individual vaccine the committee had received 503 reports of adverse reactions which included whoop-

ing cough vaccine; most reactions were however, minor.

In 1963 the number of notified cases of whooping cough started to increase again and have fluctuated about a number roughly one-fifth of the average in the decade before 1957. A survey carried out in 1969 on the whooping cough vaccines in use until 1968 suggested that although there was a marked decline in the disease, the vaccine had not been absolutely effective overall. The findings of the report suggested that in future the efficacy of the whooping cough vaccine should be kept under constant surveillance.

Since there are children definitely suffering from the effects of vaccines it would seem proper that the matter should be opened up and accurate figures revealed to substantiate the accusations now being made.

When Mr Michael Allison, Under Secretary for Health and Social Security, was questioned in Parliament on the success of immunisation he said that it could be measured by the virtual eradication of diphtheria and poliomyelitis. He also claimed that no immunisation procedure is entirely free from risk of ill-effects, even though he understood that about 170 reports of adverse reactions to vaccines of all types were received each year.

Mr Jack Ashley was not satisfied with Mr Allison's remarks and intends to submit a motion to Parliament calling for action on the cases of children harmed by administration of vaccines.

Prescribing safely for children

Fiona Selkirk

SHOULD potentially dangerous drugs be prescribed for children under the age of 10, in the hope that they may alleviate some relatively trivial complaint of childhood? This is a question often raised and highlighted once again by a recent report in the *British Medical Journal* (BMJ) (1, 261; 1974).

The report is the results of a seven and one-half year survey of the cases of accidental drug poisoning in children admitted to the Royal Hospital for Sick Children in Glasgow (carried out by Drs K. M. Goel and R. A. Shanks). Of the 60 children suffering from poisoning by one or other of two drugs (amitryptiline or imipramine), three-quarters were between the ages of two and four years, more than half were poisoned as a result of having taken an excess of the drugs originally prescribed for themselves or for brothers and sisters. Of these 60 children, 30 were admitted during the past 18 months, indicating that this situation is worsening. The remaining 43% of children suffering from the

effects of poisoning had swallowed the same drugs prescribed for adults in the family.

The drugs in question are tricyclic hydrochlorides, commonly prescribed as anti-depressants in adults, and have been found to have varying degrees of usefulness in the treatment of nocturnal enuresis (bed-wetting) in children.

There is no positive information about the toxicity of these drugs in abnormal quantities. There is no known antidote. Some people believe that serious manifestations invariably appear after ingestion but others believe that the severity of poisoning is related to individual tolerance and that the severity of poisoning should be assessed symptomatically.

Any case of accidental overdose of tricyclics in children is treated with close observation for 24 hours and the experience of the Glasgow group is that if the child survives that first critical period, it will probably recover completely, with no after effects. The symptoms presented are treated where possible. The heart is restarted mechanically; the lungs ventilated; convulsions treated with drugs and the contents of the stomach are always removed.

Opinions vary as to whether the use of these drugs has any lasting effect on the condition. Dr Shanks firmly believes that they do not. He feels that at best the effects are only transient and that it seems that as soon as treatment is stopped the situation reverts to the *status quo ante*. A general medical practitioner who has prescribed these drugs from time to time for his patients, and has found their effect "quite impressive", says the limiting factor to the duration of treatment is usually the patient. Either he comes back for a repeat prescription because "the tablets you gave him last time worked so well doctor" or he stops coming. The doctor admitted however, that he knew cases where the condition seemed to have cleared, treatment had stopped and then, perhaps six months later, the patient's mother was back in the surgery, asking for more, because the child had started being wet again.

This doctor does not believe in treating children of pre-school age but older children, who are likely to suffer socially from the effects of this condition, he believes should get whatever help he can give them. Parents should be given something positive to do, so that they feel they are being of some help to the child also.

Having been quite impressed by the effectiveness of these drugs in the treatment of enuresis in his patients, the doctor said that he was "pretty horrified" when he read of the effects that accidental poisoning seem to produce in

young children.

On the whole, doctors are at their own discretion as to what drugs to prescribe to which patients, and how much and how often the medicine should be administered. They have as guidelines the literature produced by the pharmaceutical companies marketing the drugs, reports in the medical and scientific literature, training courses at universities and colleges and, occasionally, directives from the Department of Health and Social Security, distributed through the local Executive Councils. There are many journals available free or on subscription—one such is produced by the Consumer Council—which give doctors information about medicines, contain advice on which drugs established for the treatment of one condition have a beneficial effect for a completely different disease. The pharmacologists then have to discover the reason for the link.

When doctors prescribe drugs, especially for children, they generally warn the patient of the dangers associated with the medicine and remind them of the necessity to keep all medicine out of reach of children. Dr Shanks says that when parents of children who had poisoned themselves with the drugs were told of the dangers, they were naturally very upset and many said that they had not realised just how dangerous they were. If the rationale for prescribing tricyclics for young children is that they will relieve the anxiety symptoms manifested by enuresis (and one accepts that there are occasions when their use is justified), then perhaps the warnings should be spelt out more fully.

There have always been claims for the effectiveness of some treatment for a particular disease or condition but, on the whole, the cures were not as dangerous as the illnesses. Today, perhaps, there is too much emphasis placed on a cure at all costs, or at least easing of symptoms, and the advances of the pharmaceutical industry, together with the pressures of society, are just a little too great on the doctor with the prescription pad and the distressed patient.

Congress to lose key nuclear advocates

Colin Norman, Washington

THE Joint Committee on Atomic Energy, which for years has held a tight rein on legislation dealing with all aspects of nuclear energy in the United States, is about to lose two of its most powerful, and certainly its most colourful, members. Last month, Craig Hosmer, the most senior House Republican on the committee, announced that he will be retiring from Congress at the end of the year. And last week, his comrade-

in-arms, Chet Holifield, announced that he, too, will quit national politics this year after a 32-year stint in Congress. Their departure is raising some speculation about the future for the joint committee.

Holifield, a crusty Democrat who was a charter member of the committee and its chairman in alternate Congresses between 1963 and 1971 (the chairmanship alternates between a Senator and a Congressman), has decided to step down rather than face a tough challenge in a primary election in his California constituency. In 1971, he became chairman of the House Committee on Government Operations, a move which put him in a strong position to intercept and reshape the Administration's proposals for government reorganisation, and his Joint Committee mantle then fell to Melvin Price, a Democrat from Illinois.

Hosmer, Price and Holifield between them have largely dominated the work of the joint committee since the late 1950s. They have devoted their time almost exclusively to the committee's work, often at the expense of other activities, and this has given them a depth of knowledge which their opponents find difficult to overcome. All three are strong advocates of nuclear power, and they have been constantly attacked by environmentalists in the past few years.

Thus, with two members of the troika about to depart, a leadership vacuum is likely to emerge in the committee. Whether that will diminish the committee's power on Capitol Hill remains to be seen, but other developments are likely to have a more important impact on its future role. In any case, the unique status of the committee makes it an extremely difficult body to get rid of, or even to change.

The committee derives much of its power from several factors. First, the Atomic Energy Commission has a legal responsibility to keep the committee "fully and currently informed" of its activities, a requirement which gives committee members complete access to the agency's plans and deliberations. Ralph Nader recently remarked in a hearing before the joint committee that a result of this requirement is that the committee "has acted more like a part of the executive branch than any other committee of Congress", and it is often accused of being a mouthpiece for, rather than a watchdog of, the Atomic Energy Commission.

Second, it is the only legislative committee of Congress which has responsibility for nuclear energy. Other matters are considered by separate committees in the House and the Senate, and interchange between committees is frequently important for bringing out an resolving important problems. According to the

joint committee's critics, the lack of interchange on nuclear energy matters often has the result that differences of opinion fail to surface in Congress.

And third, the committee was established by an Act of Congress, and thus its functions and structure cannot be altered unless Congress passes a bill to do so. Since such a bill would be referred to the Joint Committee, its future is entirely in its own hands.

One development could, however, have a profound impact on the committee. Congress is now considering a bill to create an Energy Research and Development Administration (ERDA), based on the laboratories of the Atomic Energy Commission, but including energy research and development programmes from other agencies. If Congress passes the bill, the AEC would be split in two—the regulatory functions would be put into a separate agency—and the joint committee would be left with authority over an agency with which many other committees would also be concerned. A bill to establish ERDA has already been approved by the House of Representatives, and is now under consideration by the Senate Government Operations Committee.

Whatever the prognosis for the ERDA bill, the joint committee will certainly be a different body without Hosmer and Holifield. Their hearing room style alone, which ranged from bitingly sarcastic to gentle bullying—but which was always incisive—will be especially missed from the committee's deliberation.

Hearing double

A CURIOUS piece of programming by the BBC on Monday February 11 produced "Scientifically Speaking" on Radio 3 commencing at 2125, and "Kaleidoscope" on Radio 4 commencing at 2130. As if this were not enough to strain credulity, listeners with two radios were then treated to a simultaneous discussion of black holes and X-ray sources, with special reference to Cygnus X-1, on each channel.

On Radio 4 Professor R. L. F. Boyd could be heard confounding the interviewer (who may have been intimidated by the knowledge that Professor Boyd is a member of the BBC's Science Consultative Group) with a moderately hairy description of the black hole phenomenon which made no concessions to the level of scientific interest of the "Kaleidoscope" audience; on the theoretically more highbrow Radio 3, the lucid discussion by Professors Martin Rees and Ken Pounds was, by contrast, so clear that confused "Kaleidoscope" listeners who switched channels hoping to catch the end of a concert might even have stayed for the end of the programme.

Is anonymity necessary?

SIR,—As co-editor of a series of books (*Comprehensive Virology*, Plenum, 1974) I was recently taken to task concerning the advisability of anonymous reviewing of solicited chapters. We fully agree with this criticism and will in the future request our reviewers to submit their constructive critical comments over their signature, so that the author can ask for clarification or defend his position.

As a past or present member of the editorial boards of several journals as well as frequent reviewer and reviewee of papers, I would like to broaden this enquiry into the effect of anonymity in the domain of reviewing for scientific journals. I was recently asked to review, and advocated rejection of, a paper for a virological journal on the basis of factual comments which I would have been quite willing to sign. The editor sent me, out of courtesy, copies of his rejection letter together with the other reviewer's sarcastic poison-pen comments, also rejecting the paper. There was no justification for one civilised person insulting another in such manner (as well as a specified alternative "boring" journal that might be willing to publish such "routine and dull work"); that outburst was solely the joy of releasing adrenaline with anonymous impunity.

I have read many other reviews which were full of bias. In one recent instance the reviewer, not wishing to accept the well proven conclusion of the author, misquoted the literature to prove his point to an editor who would not have the time to verify his citations.

I have given this matter considerable thought. There is no question that much good comes out of careful and conscientious reviewing and that scientific communication would not be improved by abolishing it altogether. But anonymity tends to bring out the worst in people and it causes undesirable aspects of the reviewing system which I believe to be unnecessary. Thus I advocate that editorial boards could and should come out strongly in favour of reviewers identifying themselves when they detect factual errors, weaknesses in the argument, inadequate or erroneous citations, or lack of clarity in a manuscript. The author can then consider these comments in the same polite and considerate style that such reviews would show.

This suggestion does not preclude the reviewer expressing his conclusions di-

rectly to the editors if he feels this to be necessary or helpful. If he advocates rejection in his letter to the editor, and if this is supported by the factual arguments given to the authors which in turn are not easily and clearly countered by them, then the scientific level of the journal would not be diminished, and the state of mind of the scientific community would be noticeably improved.

Yours faithfully

Protein Gap

SIR,—The Food and Agriculture Organisation of the United Nations and the World Health Organisation have just published jointly their latest report on energy and protein requirements of man based on a comprehensive review of 50 years research in the field. A comparison of the average requirements per person based on this report¹ with average intakes shows that there is no protein gap at the national level. In most countries the average protein intake exceeds the average requirement so considerably that inequality in the consumption also fails to explain the full extent of the incidence of protein malnutrition. Furthermore, in those few individuals whose protein intake is found to be inadequate, the deficiency of energy intake relative to requirement is even more marked. Clearly, what diets lack is not protein but energy to metabolise the protein people actually eat^{2,3} (Miller and Payne, 1969; Sukhatme, 1969). In the circumstances the United Nations call to intensify production of semi-conventional protein-rich foods for closing the so-called protein gap seems to have little to commend it to the developing countries (U.N. General Assembly Resolution 1970).

Surprisingly, however, the 1973 report incorporates a new interpretation of the meaning of protein requirement to help planners evaluate an apparently non-existent protein gap. This interpretation is that an individual eating below the recommended level, called a 'safe' level in the report (that is the average requirement plus twice the standard deviation), while not necessarily malnourished, runs the risk of developing protein deficiency and that the risk increases as the intake falls below the "safe" level.

The implication is that individuals should be counselled to eat at levels above the "safe" level and that countries should aim to increase their protein supplies to make this possible. Calculations based on the normal bivariate distribution model for intake and requirement, which is implicit in the new interpretation of requirement show that the needed increases are very large; so large in fact as to be considered "unrealistic of the situation in the developing countries"⁴. In effect this exercise implies that 97.5% of the population would have to eat at levels of overconsumption—or waste—several times greater than the average needs to limit the population at risk (that is below the "safe" level) to 2.5%. If it were not protein but some other nutrient, say Vitamin A, these levels would be in the toxic range!

Evidently the assumptions implicit in the new interpretation of requirement require careful evaluation. I have examined them and find that they are not supported by available data. In particular, I find that the basic assumption that the requirement of an individual, like his intake, is known and can be determined with an error of measurement which can be assumed to be negligible, is not borne out by the data. I find that intra-individual variability in requirement often accounts for a major part of the total variation. Consequently neglecting to take it into account gives a grossly exaggerated and misleading picture of the protein problem in the countries concerned. In a similar vein, such statements as "two-thirds of the world is hungry and malnourished" as was first suggested by Lord Boyd Orr and which continue to be repeated in evaluating the nutritional situation in the developing countries have their origin primarily in the failure to recognise the status of the variable quantified by requirement. Details will be found in Sukhatme^{5,6}.

news and views

Have tachyons been observed?

ONCE upon a time discoveries in physics were made by experimentalists who used their skills to detect the new and the unexpected. Interpretation came later. Nowadays, however, it is as often as not the theorist who takes the initiative. An existing theoretical framework may be extended in a self-consistent way that leads to quite specific predictions concerning new effects. The experimentalist is then invited to devise an experiment that will 'verify' or 'confirm' the predictions. Elementary particle physics, in particular, illustrates this trend. The pion and the Ω^- particle are famous examples of successful predictions. Particles that remain on the 'wanted' list include the legendary quarks—particles of large mass and fractional charge—and the tachyons. The quarks, if they exist, would provide a neat interpretation of the regularities observed among the known elementary particles (SU3 symmetry). The tachyons would allow one to extend the ideas of relativity into the region where velocities greater than the velocity of light occur.

In the usual interpretation of relativity, it is stated that particle velocities v can never exceed the velocity of light c . The reason is that the total energy $m_0 c^2 [1 - (v/c)^2]^{-1/2}$ must be a real quantity. To obtain a real value for the energy when $v > c$ we must suppose that the particle concerned is one for which the rest mass parameter m_0 is not a real number. Instead we must put $m_0 = im$, with m real. If this extension to the theory is physically valid, then tachyons can exist and their total energy is given by $m_0 c^2 [(v/c)^2 - 1]^{-1/2}$. It follows that tachyon velocities are restricted to the range $v > c$ and that their energy diminishes as v increases. In other words, energy loss produces acceleration. Other, somewhat bizarre, properties can be expected. A charged tachyon, for instance, automatically fulfils the conditions for emission of Čerenkov light, even in free space. It must therefore radiate energy spontaneously and suffer continuous acceleration to higher and higher velocities. It has no possibility of 'uniform motion in a straight line'.

The experimental search for tachyons is based on the supposition that they can be produced during elementary particle interactions and can subsequently cause such interactions. Some investigators have performed bubble chamber plus accelerator experiments; others have made use of the cosmic-ray flux and have looked for tachyon production in the atmosphere. The bubble chamber studies apply the requirements of energy-momentum conservation to obtain the square of the mass of an unknown particle produced in the interaction. This is standard practice. For ordinary particles, the (mass)² is, of course, positive but for tachyons the value would be negative. So far, this search has been unsuccessful. The cosmic-ray search depends on the possibility of tachyons being produced in the early stages of development of extensive air showers. Since the tachyons travel (by definition) faster than c , they must reach the ground before the shower itself. If they are capable of producing a response in ordinary particle detectors, one should therefore observe particles associated in time with the air shower but occurring some tens of microseconds earlier.

An experiment of this kind is described by Clay and

Crouch in a communication on page 28 of this issue of *Nature*. With due caution, after a careful statistical analysis of their measurements, they conclude that they have indeed "observed non-random events preceding the arrival of an extensive air shower". This result should encourage others to continue the search. Until the measurements provide something more tangible in the way of estimated cross sections and other limitations on the parameters used to describe the particle, it is unlikely, however, that they will inspire more than polite interest among theoretical physicists.

Structure of transfer RNA

NUCLEIC acid research entered a new era, when a little more than a year ago, Kim, Rich and their colleagues at the Massachusetts Institute of Technology, reported their success in the X-ray analysis of a crystalline transfer RNA. Their studies, at successively 5.5Å and 4.0Å resolution (*Proc. natn. Acad. Sci. U.S.A.*, 69, 3746; 1972; and *Science*, 179, 285; 1973), enabled the overall shape of the molecule to be determined with a fair degree of certainty. They now report, on page 20 of this issue of *Nature*, their latest results at an increased resolution of 3Å, and their new electron density maps reveal considerably more detail than hitherto. Thus, whereas at 4Å, the ribose-phosphate groups were discernible as individual peaks, the higher resolution data have enabled these to be resolved into two separate peaks, in many instances with a consequent increase in the confidence of the electron density interpretation.

The dominant feature of the 4Å model of Kim *et al.*, in which the molecule has an overall L shape, has been amply confirmed in the new electron density maps. The course of the polynucleotide chain was followed by tracing the characteristic ribose-phosphate zig-zag which was clearly seen in many places, especially double-helical regions. Base pairs also can be easily observed in many regions, and the double-helical parts of the molecule are all well resolved, although one base cannot be distinguished from another. Difficulties were evidently encountered, however, when they tried to follow the course of the chain in the non-helical regions of the molecule—the so-called loop segments. These seemed to be due partly to chain irregularities, and also to ambiguities in the maps in these regions arising from extraneous peaks which the authors ascribe to bound cations. The two loops, pseudouridine and dihydrouracil, which are somewhat crowded together close to the corner of the L, suffer especially from these uncertainties. Likewise, the CpCpA acceptor stem of the tRNA molecule is not well defined, though this may be a consequence of the inherent flexibility and sloppy nature of this grouping.

Several other details that were not apparent in the earlier low resolution studies have emerged. Previously the molecule was seen to have the two arms of the L consisting of two roughly perpendicular double-helical branches, each of which consisted of two colinear stems. This picture has had to be modified so that now only one branch has colinearity, the other has the anticodon and the dihydrouracil stems mutually inclined at an angle which may be as much as 30°.

It is perhaps not too surprising, in view of their shortness, that none of the four helical stems has been found to be quite regular, and that they cannot be described in terms of exact helical parameters. The authors have also been able to distinguish various other interesting features of these stem regions; thus, purine bases at the end of the helices often lie in stacked arrangement with respect to them. Similarly, the G-U base pair which lies in the middle of the CpCpA stem is also stacked parallel to the other double-helical bases in this region. The anticodon loop of the tRNA molecule, which is involved in coding recognition during protein synthesis, is seen to have the bases on the outside of the loop, although, again, there are uncertainties here.

It is unfortunate that the features of tRNA that are of greatest functional interest are so far poorly resolved. The MIT workers are now extending their analysis to include all the reflections occurring in the diffraction patterns, which extend to a resolution of 2.3Å. It is to be hoped that this work, together with additional heavy-atom derivatives to improve the phasing, will result in a good definition of the complete molecular structure.

The next stage in tRNA crystallography—the structural analysis of species other than the yeast phenylalanine tRNA of Kim *et al.*—still seems some way off. Only then will one really be able to discuss the relations of tertiary structure to biological function by correlating structural features common between tRNAs. S.N.

Towards a more efficient use of cytotoxic agents

BIOLOGISTS who seek, by the introduction of defined chemical agents into the body of man to alleviate, remedy or cure its many ailments, have a peculiarly mixed credo. There are the "eye of newt and toe of frog" experts (*Macbeth*, Act IV, Scene 1) who are happy if they can produce a relatively effective agent which does not have any apparent and immediate side effects. Others, pursuing the notion of "sufficient unto the day is the evil thereof" (*St Matthew*, VI, 34) have devised agents of known toxicity which despite their side effects and lack of specificity are nevertheless used as the only ones available. In a situation where there are very few medicaments whose effects can be thoroughly understood, it is reasonable that the art of expediency should have been practised. On page 82 of this issue of *Nature* appears an article by Rubens and Dulbecco which is one of a series of attempts to provide a more rational basis for chemotherapy—in this instance of cancer.

Many cytotoxic agents have been used to attack cancer cells. In all instances there have been undesirable side effects on vital organs such as bone marrow so that the clinician has always had to consider the balance between desirable tumour cell eradication and potentially lethal toxicity. Attempts have been made to improve the specificity of action of these agents so that their cytotoxicity is concentrated in malignant cells. Ingeniously prepared 'latently active' agents which are themselves quite non-toxic but which can transform to toxic products selectively in tumour cells have been synthesised. Another approach has been to use larger molecular weight materials as carriers of the cytotoxic chemicals. Daunorubicin, for example, is more effective against the L1210 leukaemia in mice if it is administered as its intercalated complex with DNA (Trouet, Deprez-de-Campeneere and de Duve, *Nature new Biol.*, 239, 110; 1972). The complex seems to be taken up selectively by tumour cell endocytosis. Inside the cell the DNA of the complex is digested by lysosomal enzymes and the daunorubicin is released in its active form and attacks nuclear DNA.

The results in the laboratory have been of sufficient interest to lead to a clinical trial of the complex in the treatment of myeloid leukaemia (Sokal, Trouet, Michaux and Cornu, *Eur. J. Cancer*, 9, 391; 1973). Proteins have also been used as carriers of anti-cancer agents and albumin has been shown to be selectively incorporated into tumour areas (Busch and Greene, *Yale J. Biol. Med.*, 27, 339; 1955). Similarly, fibrinogen seems to concentrate in the necrotic regions of tumours (Islaker, Cerottini, Jaton and Magnenat, *Chemotherapy of Cancer*, edit by Plattner, Elsevier, Amsterdam, 1964) and attempts have been made locally to irradiate cancers by the use of radioactive iodinated fibrinogen and anti-fibrin antibody. Globulins, fibrinogens and albumins have been covalently bound to alkylating agents and antimetabolites in a further attempt to concentrate the cytotoxic agent in tumour cells (Wade, Whisson, and Szekerke, *Nature*, 215, 1303; 1967; Mathe, BaLoc and Barnard, *C. r. hebdom. Séanc. Acad. Sci., Paris*, 246, 1626; 1958; Larsen, *Eur. J. Cancer*, 3, 163; 1967). In some instances covalent attachment to protein has increased the selectivity of action of the anti-tumour agent. One interesting finding was that nitrogen mustards merely absorbed (and not covalently bound) to protein could also be more selective than the mustard alone (Wade *et al.*, *loc. cit.*).

An extension of this work and one more likely to give greater specificity has been to attach cytotoxic agents to tumour specific antibodies. Alkylating agents conjugated to antibody directed against tumour cell antigens have been quite effective (Ghose, Cerini, Carter and Nairn, *Brit. Med. J.*, 1, 90; 1967), but more surprising has been the finding that the alkylating agent chlorambucil merely absorbed to an immunoglobulin fraction is a much better inhibitor of an experimental tumour than either chlorambucil alone or absorbed to a normal globulin fraction (Ghose, Norvell, Guclu, Cameron, Bodurtha and MacDonald, *Brit. Med. J.*, 3, 495; 1972). This is surprising since the absorbed alkylating agent would be expected to dissociate from the globulins on injection. The basis for the improved selectivity is thus not at all clear, but the results have been confirmed by the related work of Flechner (*Eur. J. Cancer*, 9, 741; 1973) who showed that anti-Ehrlich ascites globulin complexed with chlorambucil could cure mice bearing the Ehrlich ascites tumour.

In an attempt to explain this phenomenon, Rubens and Dulbecco (this issue) have shown that chlorambucil and a tumour specific globulin are indeed synergistic but that there is no requirement for physical absorption between the two since separate addition of the two components can still bring about the desired effect.

Obviously the cytotoxic agent and the tumour specific globulin act together, but not by the protein acting as a carrier. The mechanism once elucidated may lead to more efficient use of the cytotoxic agents in the treatment of cancer.

C-type viruses of primates

BIOLOGISTS who hanker after new species of organisms may profitably examine primates for hitherto undiscovered viruses. In recent years more than twenty new herpesviruses have been described, and now several groups under contract with the Virus Cancer Program of the US National Cancer Institute have detected RNA tumour viruses in normal or malignant tissues of primates.

The first virus, known as Mason-Pfizer virus, was isolated by Chopra and Mason (*Cancer Res.*, 30, 2081; 1970) from a mammary tumour of a Rhesus monkey. The Mason-Pfizer virus has a morphology intermediate between the B-type

(mammary tumour viruses) and C-type (leukaemia-sarcoma viruses) characteristic of mice and other vertebrates. Then a C-type virus was isolated from a sarcoma of a woolly monkey by the comparative oncology group at the University of California at Davis (Theilen *et al.*, *J. natn. Cancer Inst.*, **47**, 881; 1971) and this virus was found to induce sarcomas when inoculated into marmosets (Wolfe *et al.*, *J. natn. Cancer Inst.*, **47**, 1115; 1971).

The Davis researchers also isolated a C-type virus from a lymphosarcoma of an ape, the white-handed gibbon (Kawakami *et al.*, *Nature new Biol.*, **235**, 170; 1972). Several lymphomas and leukaemias of gibbons have been reported lately, and C-type particles have also been observed in the only other one examined (Snyder *et al.*, *J. natn. Cancer Inst.*, **51**, 89; 1973). These observations, however, apply to gibbons which have been kept in captivity for several years and some have been subjected to experimental procedures such as X irradiation which may have rendered those animals susceptible to unusual infections. Immunological and nucleic acid hybridisation studies indicate that the viruses isolated from the woolly monkey and the gibbon are very closely related. Considering how widely separated in evolution and geographical distribution are the New World monkey and the ape, it seems possible that at least one of the C-type viruses has been acquired in captivity from another source, rather than that they represent natural infections for both species.

Three recent reports describe C-type virus particles associated with primate placental tissues. Schidlovsky and Ahmed of Pfizer Inc. (*J. natn. Cancer Inst.*, **51**, 225; 1973) observed particles by electron microscopy budding from the syncytial trophoblast in each of four Rhesus monkey placentae and also in erythroblasts of foetal haemopoietic tissues. Kalter and his colleagues at the Southwest Foundation for Research and Education, Texas (*Science*, **179**, 1332; 1973) independently observed C-type particles associated with the placenta of baboons. The virus particles were prevalent at the syncytial trophoblast of each of thirteen normal baboon placentae at various stages of gestation. These findings naturally led Kalter and his colleagues to investigate human tissue (*J. natn. Cancer Inst.*, **50**, 1081; 1973) in which they also claim to see C-type particles, though very few in number, in four of six human placentae. Each placenta required several hours of screening with the electron microscope before particles plausible enough for publication were photographed.

Kalter generously provided a baboon placenta to Todaro's laboratory at the

US National Cancer Institute and the isolation in infectious C-type virus is reported in this issue of *Nature* (page 17). The placental tissue was cocultivated with various mammalian cell lines and virus was found to replicate most efficiently in a canine thymus cell line. Molecular hybridisation studies using complementary DNA transcribed from the RNA of the propagated virus do not indicate any homology between the baboon virus and other C-type viruses, including those isolated from the woolly monkey and gibbon. There is, however, substantial homology with DNA extracted from normal baboon placenta and liver and with RNA extracted from the placenta.

These results suggest that the C-type virus represents an endogenous, vertically-transmitted virus of baboons, that is normally expressed in the syncytial trophoblast but not in most other tissues. No doubt several laboratories are now busy cocultivating human placental tissue with every mammalian cell line that comes to hand in the hope of propagating an endogenous human C-type virus. They may well be successful.

Replication in synchronised cells

from a Correspondent

Non-random DNA replication during S phase of cultivated cells has been known since the early days of autoradiography. Moreover, analysis of the replication time of easily purified specific DNA sequences, such as the nuclear satellite DNAs found in many species of animals and plants, suggests that the ordering of replication is regulated by the DNA sequences involved. Although the exact point of replication of a particular DNA sequence may depend on the physiological state of the cell—for instance normally mouse satellite DNA replicates late in S phase but it seems to replicate in early S phase in cells infected with polyoma virus (Smith, *J. molec. Biol.*, **47**, 101; 1970)—it seems to be constant from one cell generation to the next.

Several descriptions exist for the replication time of the multiple genes for ribosomal RNA but they may be criticised on two grounds; one is lack of sensitivity of the technique used for assaying rDNA and the other is the inadequacy of the technique used for synchronising the cells. In a recent issue of the *Journal of Molecular Biology* (**82**, 303; 1974) Stambrook reinvestigates the temporal replication of ribosomal genes. He used Chinese hamster ovary cells synchronised by the 'wash off' procedure for collecting cells in meta-

Last of the line

THE publication of part XXXI of Stella Ross-Craig's *Drawings of British Plants* (Bell, 1973) brings to an end a series which started life in 1948 with Ranunculaceae and which has covered all British flowering plants except the Cyperaceae and the Graminae which have been illustrated adequately elsewhere. Lemnaceae (duckweed), Alismataceae (water plantain), Juncaginaceae (arrow grass), Potamogetonaceae (pondweed) and Zosteraceae (grass wrack) are among the families included in the last part. This figure shows the form of the ivy-leaved duckweed *Lemna trisulca*.

phase together with a highly sensitive assay for newly synthesised rDNA. Synchronised cells were labelled with bromodeoxyuridine (BUdR) for successive intervals of 2 h covering the 8 h duration of S phase and the DNA was isolated. Newly replicated DNA will be labelled with BUdR in one strand and will band in a neutral CsCl gradient at a greater density than the unreplicated DNA. Following banding in CsCl gradients, DNA fractions were denatured, loaded on to filters and challenged with a very high specific activity complementary RNA made *in vitro* using purified *Xenopus* rDNA and *Escherichia coli* RNA polymerase. The proportion of rDNA replicating during the BUdR pulse is equal to the proportion of cRNA hybridising to high density DNA, and the proportion of total DNA replicating during the same 2 h is given by the proportion of total optical density banding at high density. Although the nucleic acid hybridisation reaction is heterologous, Stambrook found that it has high fidelity. The cRNA is competed to a high level with Chinese hamster rRNA and also hybridises to a high density

component of total DNA in the same position as authentic ^3H -labelled Chinese hamster RNA.

Stambrook found that approximately 50% of rDNA replicates during the first 2 h of S phase during which time only 27% of the bulk DNA replicates; most of the remaining rDNA, together with 36% of the bulk DNA, replicates during the next 2 h. Studies with other mammalian cell systems have given very different results, for instance HeLa cells replicated ribosomal genes during the whole of S phase (Balazs and Schildkraut, *J. molec. Biol.*, **57**, 153; 1971) and rat kangaroo cells replicated them at the end of S phase (Giacanami and Finbel, *J. molec. Biol.*, **70**, 725; 1972). It is possible that the lack of a discrete replication time in HeLa cells results from a breakdown of some regulatory mechanism which coordinates the replication of rDNA and which is responsible for the apparent synchrony of replication of rDNA in other cells. A more likely explanation, since the multiple ribosomal genes in HeLa cells are localised on five separate chromosomes whereas those of Chinese hamster and rat kangaroo are probably located on one chromosome, may be that coordination of replication is related to locus, separate loci being under independent control. Although against this interpretation is the observation that satellite DNAs are spread over several chromosomes and replicate together at the end of S phase.

One criticism of Stambrook's experiments is that there is no indication of the molecular weight of DNA used in the CsCl gradients. It could be argued, since ribosomal RNA coding sequences are known to be intermingled with spacer DNAs of approximately equal length, that early replication of spacer DNA in the absence of replication of ribosomal RNA coding sequence would lead to the latter banding at higher density. Banding of DNAs with molecular weights less than one complete rDNA repeat unit (8×10^6 daltons) should in principle distinguish this possibility.

Stimulation of tumour cells by antibody

from a Correspondent

THE ways and means by which the immune system elects the destruction of tumour cells have always held centre stage in tumour immunology, but a gentle push towards the wings now seems to be in the making. That push is being exerted by immunologists who maintain that the immune response, in addition to its ability to inhibit tumour growth, can—in the appropriate conditions—

stimulate it. This immunostimulation theory was first put forward by Prehn a few years ago, the essence of it being that a weak immune response could encourage growth of nascent tumours, whereas a more potent immune response could effect the opposite result.

How this effect might occur is the subject of a paper by Shearer, Philpott and Parker in a recent issue of *Science* (**182**, 1357; 1973); the authors studied the effect of adding specific antisera to various cultures of human or mouse tumour cell lines. In all cases it was found that the addition of small concentrations of antibody brought about enhanced cell growth, as assessed by increased cellular incorporation of radioactive precursors of nucleic acids. Conversely, high concentrations of antibody inhibited cell growth, effects which clearly mimic Prehn's earlier *in vivo* studies on the effect of transferring high or low numbers of immune lymphocytes along with tumour cells into a non-immune host (*Science*, N.Y., **176**, 170; 1972). Furthermore, the authors found that the effect could be duplicated by coupling a chemical haptenic group to the tumour cells and subsequently adding various amounts of antibody with specificity for the chemical grouping to the cell cultures.

These results, taken together with Prehn's, clearly indicate that antibody molecules against tumour cell surface components can induce alterations in growth behaviour which are strikingly similar to those seen when lymphocytes are used as target cells, and imply yet another mechanism by which antibodies can enhance tumour growth.

An afterthought of these experiments is whether antibody of irrelevant specificity, if it can be made to interact with a tumour cell, will induce a similar kind of stimulatory effect. Such a union is made plausible by the surprising demonstration that a variety of non-lymphoid tumours in the human have receptors for antigen-antibody complexes (so-called Fc receptors) which recognise the Fc region of immunoglobulin molecules when complexed to specific antigen (Tønder and Thunold, *Scand. J. Immunol.*, **2**, 207; 1973). Such receptors have been described as an array of cell types including macrophages, mast cells, granulocytes, neutrophils and lymphocytes. Furthermore, it is well known that immune complexes can stimulate cell division of lymphocytes *in vitro*. Considering the similarity of certain populations of tumour cells and lymphocytes with regard to the effects that specific antibody on their growth characteristics, as well as the presence of Fc receptors, it might not be too surprising to find that certain kinds of immune complexes can stimulate or inhibit tumour cell growth.

Do mantle plumes produce copper?

from our Geomagnetism Correspondent

ALTHOUGH the various hypotheses making up the new global tectonics have combined to form a viable framework for the behaviour of the Earth as a whole, much still needs to be done in interpreting more local geological data in terms of the wider, and hopefully unifying, concepts. Indeed, the job of interpreting new data and reinterpreting the old is likely to be the main preoccupation of Earth scientists for many decades to come, not only in connection with 'pure' geological phenomena but also as a first step towards more successful methods of prospecting for mineral resources. But there are dangers, for in spite of the success of the new global tectonics, some of the basic concepts involved are still matters of dispute; and a too premature and uncritical application of them in more localised situations could easily lead geology, and especially economic geology, into a series of costly blind alleys.

The problem is well illustrated by Livingston's attempt (*Earth planet. Sci. Lett.*, **20**, 171; 1973) to reinterpret the formation of porphyry copper deposits in the south-western United States in terms of the activity of a mantle plume. The deposits in question are "geochemically distinctive petrological entities" containing anomalously high concentrations of copper, sulphur, molybdenum, gold, silver and rhenium, and are related genetically to the intrusive phases of intermediate to silicic volcanic complexes. Potassium-argon dating, for example, has shown that the igneous intrusion and the metallisation were very close in time. On the other hand, there are both barren and productive intrusions with similar lithophilic element compositions, which leads Livingston to suggest that the formation of those intrusives carrying metallic sulphides of commercial significance is governed by some "unique factor". This unique factor, he then claims, is a mantle hot spot, although this does not necessarily mean that the sulphur and metals are derived directly from the deep mantle.

The chief evidence in favour of metal formation by hot spot comes from the distribution of the deposits in space and time. All of the porphyry deposits considered by Livingston have potassium-argon ages in the range 52–72 million years, which is identical to the range of ages for the associated volcanic and intrusive rocks and coincident with the time span of the classical Laramide orogeny. But when the ages of the individual deposits are

examined in greater detail, they are not found to be distributed completely randomly within the geographical area concerned. Although there is considerable overlap there is a definite trend of decreasing age to the south-east (actually S40°E), a pattern which Livingston concludes could not be due to slow cooling. Instead, it appears that the "source" of the deposits moved towards the south-east at a rate of $3.57 \pm 0.65 \text{ cm yr}^{-1}$ —a rate sufficiently typical of plate motions to suggest that such motions are responsible for it.

The first plate tectonic feature to come to mind in this connection is the postulated subduction zone off the Pacific coast of Baja California, but although this is of the right age it would be unlikely to produce deposits whose ages vary along a line parallel to it. The alternative is a magma source which either moves towards the south-east in the lithosphere or asthenosphere, or remains stationary in the asthenosphere or mesosphere as North America moves north-westerly above it in response to global tectonic forces. The latter, adopted by Livingston as the simplest hypothesis, is a mantle plume which, taking account of the areal spread of the copper deposits, had an apparent surface diameter of 450 km. As far as the existence of copper emplacements is concerned, it also had a rather limited life of about $20 \times 10^6 \text{ yr}$, although the discovery of further evidence extending its existence cannot yet be ruled out.

On the wider scale, Livingston admits that the direction of plate motion implied by his hot spot appears to be inconsistent with the motions postulated by Dietz and Holden (*J. geophys. Res.*, **75**, 4939; 1970) and Phillips and Forsyth (*Bull. geol. Soc. Am.*, **83**, 1579; 1972) but suggests that his data represent motional details not resolved by "the more generalised approach". More critically perhaps, there is an apparent inconsistency with the directions of North American plate motion postulated by McGregor and Krause (*J. geophys. Res.*, **77**, 2526; 1972) and others. McGregor and Krause, for instance, assuming the Corner Seamounts of the North Atlantic to be the result of a hot spot, concluded that part of the North Atlantic moved in the S65°W direction subsequent to $74 \times 10^6 \text{ yr}$ ago. In fact, Livingston is able to show that this motion and his data are consistent if during the relevant period the North American plate rotated in a clockwise direction at an average rate of 0.35° per 10^6 yr about a pole located at about 50°N, 64°W, although to the extent that these figures are based on only two supposed plume traces they are probably not too accurate. Finally, Livingston claims that

his hypothesis is consistent with the available palaeomagnetic and palaeoclimatological data.

It is all so plausible; yet at the same time it somehow lacks conviction. Livingston is certainly right to document the degree to which the relevant data are consistent with the hot spot hypothesis, but for the time being it should be remembered that the very existence of hot spots and mantle plumes is widely disputed. The hot spot/mantle plume, though the least widely accepted of the phenomena associated with the new global tectonics, may ultimately become a part of the geological consensus. In the meantime, however, the dangers of introducing more and more of them to account for more and more localised phenomena should not be overlooked.

Attaching to the membrane

from our
Molecular Genetics Correspondent

ANY idea that the chromosome of *Escherichia coli* might possess only an indistinct structure was dispelled by the report of Stonington and Pettijohn (*Proc. natn. Acad. Sci. U.S.A.*, **68**, 6; 1971) that it can be recovered from lysed cells as a compact structure sedimenting very rapidly, and further rebutted by Worcel and Burgi (*J. molec. Biol.*, **71**, 127; 1972) who found that this structure is organised in a particular manner. Worcel and Burgi suggested a model in which the *E. coli* chromosome is highly folded, with from 12–80 loops each maintaining a supercoiled structure; the loops may be attached to a core of RNA. Variations in the size of the folded chromosome (from 1,300–2,200S) were attributed to differences in the amount of DNA present, this depending on its state of replication. In an extension of this work, Worcel and Burgi now turn their attention to the membrane attachment of the folded chromosome and its relationship with the replication of DNA in the cell cycle (*J. molec. Biol.*, **82**, 91; 1974).

Two types of folded chromosome particle can be obtained from *E. coli* cells depending on the conditions of lysis. At low (0–4°C) temperature, the released particles sediment at 3,000–4,000S, whereas at room temperature the folded chromosomes sediment at 1,300–2,200S. At intermediate temperatures, both types of particle are found in the same lysate and can so be directly compared. Examining these two types of particle, Worcel and Burgi found that the protein:DNA ratio is, always some ten times greater in the heavier class; the amount of nascent RNA (corre-

sponding to the entire cellular content) remains the same. The dense particles appear to represent chromosomes attached to the membrane, whereas the lighter ones correspond to chromosomes not so attached. (Worcel and Burgi suggest the nomenclature "membrane-attached chromosomes" for the heavy preparation and "folded-chromosomes" for the lighter preparation.) Folded chromosomes can be released by solubilising the phospholipids of the membrane-attached chromosomes. Core RNA polymerase is the main protein in the released folded chromosomes, but the membrane-attached chromosomes have in addition a large content of membrane proteins.

Membrane-attached chromosomes cannot be obtained from cells which have been starved for amino acids (this treatment allows completion of current rounds of replication but prevents initiation of new rounds); all of the DNA from these cells sediments as the light form of the folded chromosome. But when leucine is added to the starved cells, the chromosomes appear to re-attach to the membrane. Although there is a lag of 30 min before replication recommences after the addition of leucine, all the chromosomes become membrane-attached within 20 min. And when amino acid starvation is imposed during replication, chromosomes continuing DNA synthesis appear to remain attached to the membrane. Association of the folded chromosome with the membrane thus seems to be directly related to DNA replication.

Earlier experiments have, of course, suggested that the origin and replicating forks of bacterial DNA are enriched in membrane fractions. But there are technical difficulties which make qualifications necessary in the interpretation of almost all of these experiments. To provide a critical test of the hypothesis originally proposed by Brenner, Jacob and Cuzin in 1963 (*Cold Spring Harb. Symp. quant. Biol.*, **28**, 329), that the replicating chromosome of *E. coli* is attached to a site on the cell membrane and that attachment to this site could be the critical event which controls cycles of replication, therefore requires, as Worcel and Burgi point out, experiments utilising procedures which do not alter the properties of the membrane-DNA complex as the cell is lysed. Just such criteria seem to be met in these latest experiments.

The reason for the increased sedimentation velocity of the membrane-attached form of the chromosome is not known, but may be due to either or both of the extra mass of the membrane fragments attached to the DNA or its mode of folding. In a second article, Delius and Worcel report electron-micro-

croscopy of the two types of chromosome preparation (*J. molec. Biol.*, **82**, 107; 1974). Both exhibit highly folded and tightly supercoiled DNA. The membrane-associated chromosomes show DNA fibres attached to one or two membrane patches and, since no free ends can be seen, the DNA is presumably intact in its usual circular state. The folded chromosomes seem to be less stable, more frequently generating breaks in DNA during preparation.

The topological problems posed by this compact structure of the chromosome remain formidable. Since strands of RNA can be seen in the folded structures, transcription must take place from sequences of DNA within the particle. Similarly, replication seems to proceed while the chromosome retains its compact structure. How DNA is able to unwind for these processes and how two daughter chromosomes may separate are among the most intriguing of the topological questions as indeed are problems concerning the access of enzymes and regulator proteins to particular sequences of DNA within the chromosome structure.

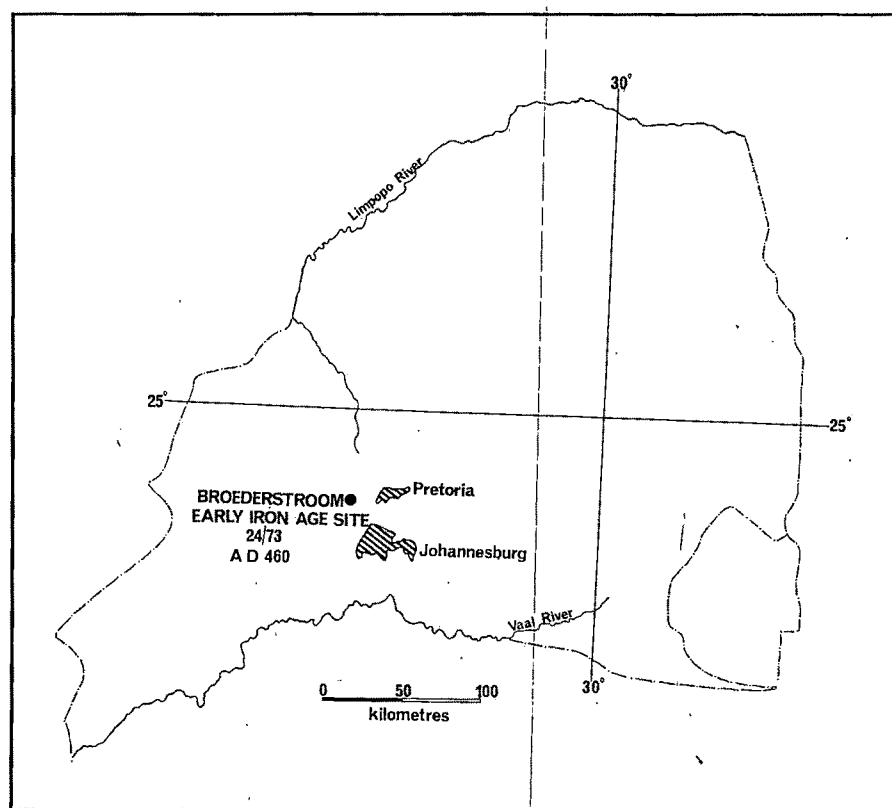

Early evidence of South African negroid

from a Correspondent

THE outline of an Iron Age village, which may represent the earliest and most intact village yet found in Africa south of the Sahara, has been discovered at Broederstroom near the Hartebeespoort Dam in Transvaal by a team led by Professor Revil Mason of the University of the Witwatersrand. The excavations followed up initial reports by Dr A. van Genderen who found the site. The material uncovered includes the earliest evidence of the South African negroid yet found and possibly also of domestic cattle.

The excavations at the site (no. 24/73) were conducted during the summer of 1973 in the grounds of the Leiden Observatory on the south bank of the dam and exposed thirteen huts and two iron slag floors on the perimeter and interior of an ellipse enclosing approximately 15 acres. No trace of stone walls was found suggesting that the village was enclosed by stockade. Among other material recovered were many thousands of sherds, a copper chain, disk ostrich shell beads, a cowrie shell, many hundreds of sandstone artefacts with 8-10 mm grooves (apparently for making shell beads), a few grindstones and some human remains.

Mason believes that the pottery was influenced by first millennium AD Iron Age pot makers in Zambia and in Malawi at Nkope and even as far north

as Kwale in Kenya, and that it is also related to pots made in the coastal regions of Natal and as far south as Pondoland, where pottery similar to that in the 24/73 assemblage was found in the 1930s by J. F. Schofield. The single cowrie shell also suggests contact with the coast. The Broederstroom pottery form includes pots with everted rims, bowls with carinated profiles and curiously thickened rims, lugs and one spout. Decoration is broadline incision of triangular punctate only; stamping is absent.

The human remains suggest links with first millennium burial ritual at sites in northern Tanzania reported by Odner (*Azania*, **6**, 89; 1971.) Part of a maxilla of an adult human lying on the base of a clay pot next to part of a mandible of a 6-12 year old child, and parts of a human leg skeleton were recovered. These remains, according to Professor J. van Reenen of the University of the Witwatersrand School of Dentistry, fall within the range of present-day South African negroids, and, with a radiocarbon date of AD 460 \pm 50 (obtained by R. Protsch at the University of California, Los Angeles), they are the earliest evidence of the South African negroid yet found.

Sheep or goat mandibles and molars of domestic cattle were also recovered and were identified by R. Welbourne. The cattle molars may be the earliest trace of domestic cattle yet found in South Africa, but their stratigraphy requires confirmation by the excavations planned for 1974. No plants were found during 1973, but it is possible

that flotation methods may reveal them during the next season.

Mason is confident that site 24/73 represents the earliest relatively complete settlement known to date in southern Africa, and that the pottery and burial methods indicate links with first millennium AD Iron Age cultures as far north as Kenya. The size of the slag floors, approximately 8 x 4 m each, and the quantity of grooved stones for bead making, suggest production in excess of local needs and may indicate trade links with neighbouring settlements not yet discovered. Mason has found similar pottery in Kruger Cave at Olifantsnek approximately 58 km west of the new site, and also near Thabazimbi 140 km north of 24/73. These records, together with those of other scattered Iron Age sites in Transvaal and Swaziland (see Mason, *Curr. Anthropol.*, **14**, 485; 1973), suggest that Iron Age settlement of South Africa during the first millennium AD was widespread. With the evidence of Broederstroom 24/73, archaeologists will now be able to relate these records to a village organisation of a kind associated with present-day Bantu speaking people in the rural regions of southern Africa.

How oil spills may affect the tundra

from our Plant Ecology Correspondent

THE exploitation of the oil fields in arctic North America has led to an increasing demand for information relat-

ing to its possible effects on the flora and fauna of the tundra biome. It is feared that the peculiar structure of tundra soils may render the system more sensitive to disturbance than has proved to be the case in more temperate climes. Below a depth of between 35 and 60 cm the soil is permanently frozen; the 'active layer' above this thaws and freezes according to the season. The application of physical pressures in the form of heavy vehicles is one form of disturbance which could upset this delicate system. Bellamy, Radforth and Radforth (*Nature*, 231, 429; 1971) found that vegetation in wet areas regenerated well following compaction—ruts disappeared within 5 years—but ruts in dry areas were still distinct even after 20 years.

Damage to surface vegetation in tundra could have more than aesthetic significance; erosion of the superficial layers of peat could have economic repercussions if vehicular transport became difficult and communications were affected.

Attention has now turned to the outcome of oil spills in such terrain, for in time such an event must be inevitable. Not only is it liable to be toxic to the surface vegetation, but it could also influence the radiation balance of the system with possible effects on the permafrost. Wein and Bliss (*J. appl. Ecol.*, 10, 671; 1973) have now described the outcome of experimental spills of crude oil in the Mackenzie Delta area of north-west Canada, 115 km from the Arctic coast. They chose different plant community types for their experiments, ranging from black spruce-alder communities on frost mounds to low lying sedge hollows in ice-wedge polygons. Plot sizes were between 3 × 4 m and 5 × 5 m depending on the community type, and oil was applied at various levels equivalent to 0.25 cm up to 1.50 cm. The second application is equivalent to 1,950 barrels per acre. Evaporation rates were estimated from open containers of oil, and temperature profiles in the peat together with the depth of the active layer were recorded.

Summer evaporation rates of oil were high, up to 15% volume losses being recorded within 16 h of application. Since many of the most phytotoxic components of crude oil are volatile aromatics, one suspects that this reduces the potential harm done by summer spills. On the other hand winter spills may not affect deep roots which are protected by permafrost. All lichens and all mosses except *Polytrichum juniperinum* were killed, and there was no recovery even a full growing season after application. The recovery of the remaining vegetation varied with species and with the level and season of applica-

tion; for example, *Carex* (sedge) species recovered less well following late season applications, whereas *Salix* (willow) species recovered better after autumn spills. In general it was the willows, birches and *Ledum palustre* (Labrador tea) which recovered most effectively from the oil applications. Total plant recovery was occasionally as great as 55% one growing season after the spill, which suggests that recovery of vegetation is best allowed to occur naturally, without further interference.

Temperature measurements showed that areas affected by spills absorbed more energy, so warming superficial layers. Increases in temperature, however, did not occur at great depth within the peat and the depth of the active layer was not affected. Probably much energy was lost in latent heat of evaporation and the drying surface peat would form an insulating cover over the cold, deeper layers.

It seems, then, that the tundra can probably cope with occasional, acute pollution from oil spills. It would be interesting to know whether this ecosystem can also survive low intensity, chronic pollution from the small spills which will inevitably be associated with the exploitation of these fields.

Half life of heavy chain message

from a Correspondent

IN estimating the turnover rate of mammalian messenger RNA there are two main problems—choice of suitable chase conditions and specific isolation of messenger RNA molecules for defined products. The presence of large pools of nucleotide precursors within eukaryotic cells creates obvious problems in a standard pulse-chase type of experiment. Decay of messenger in the presence of a metabolic inhibitor, for example actinomycin, is no longer considered to be satisfactory since the presence of drugs may cause generalised cellular malfunction so that synthesis and processing of RNA within such cells are abnormal.

Cowan and Milstein (*J. molec. Biol.*, 83, 469; 1974) have approached the question with specific reference to the RNA species which codes for the heavy and light chains of an immunoglobulin secreted by a tissue culture-adapted mouse plasmacytoma. The cells were labelled with ³H-uridine continuously during a period of 24 h in an automatic apparatus (see Cowan and Milstein, *Biochem. J.*, 128, 445; 1972), which allows the authors to calculate dilution due to growth, and thus correct the figure for RNA decay during the chase period.

Since no single chase procedure is entirely satisfactory several different conditions were studied. Cells were chased simply by the addition of cold uridine to the medium (the disadvantage of this procedure is continued and significant incorporation of low specific activity uridine during the chase which results in an overestimate of the messenger RNA half life). Alternatively, the cells were removed from the medium containing the isotopic uridine by centrifugation, and then resuspended in fresh medium containing 0, 0.1 or 0.2 M uridine. Exposure of the cells to uridine, however, causes appreciable swelling, and centrifugation is followed by a lag period of 3 h before re-entry into logarithmic growth. The messenger RNA molecules for heavy and light chains were purified by sucrose density gradient centrifugation of the microsomal extract, followed by selection of poly(A)-containing molecules using oligo(T)-cellulose. Purity of the heavy chain messenger was not known, and the light chain mRNA was 30% pure.

When radioactive uridine was removed for the chase period, similar half-lives for both heavy and light chain messenger preparations (12–14 h) were recorded whether cold uridine was present or absent. Thus, although none of these conditions is entirely satisfactory, the fact that the different chase conditions yielded similar results would suggest that the half-life values obtained were meaningful. Not unexpectedly the half-lives were longer (17–18 h) when the chase was done without removal of the radioactive uridine.

All of these values are much longer than those based on immunoglobulin synthesis in myeloma cells grown in the presence of actinomycin, probably indicating the unreliability of the actinomycin chase procedure. As the authors themselves clearly indicate, a crucial point is the purity of the messenger samples. Thus, values in the range 5–20 h cannot be excluded for the light chain message. Until the purity of the heavy chain message preparation is known, it would be premature to accept the half-life given as definitely that of heavy chain message. With increasing refinements in message RNA isolation and characterisation this question should be answered shortly.

Is Viking 1979 a possibility?

from our Cosmology Correspondent

THERE may be enough bits and pieces left over from the planned 1975 Viking missions to Mars to provide a low cost mission in 1979. Less probable, but still being actively considered, is a mission

including a Mars Rover, which could fly in 1979 or 1981 and would again use any spare parts from backups for the 1975 mission.

The 1975 missions will involve two landers and two orbiters, and a third lander is being built as a backup; this lander will, if all goes well, be available for a one-off mission in 1979, when an orbiter could be assembled from spare parts for the Viking 75 orbiters, according to a report in *Aviation Week and Space Technology* (February 11, page 56; 1974). This one-off mission would cost only some \$250 million to \$300 million, including the cost of a new scientific package. If a double mission like that of 1975 were to be attempted, one complete set of orbiter and lander would have to be built from scratch and this would push the total cost up to around \$500 million.

But perhaps the more intriguing possibility is that a Mars Rover vehicle could be added to the mission, at greater cost but without great technical difficulty. The estimated total cost of such a lander is some \$80 million and it is possible that the European Space Research Organisation (ESRO) would participate in this if the project goes ahead. Unfortunately, however, ESRO prefers the 1981 target date and this would involve NASA in much more expense, because of the need to keep Earth-based communications and staff available for another two years.

There is also the problem that NASA would like to do something in 1979 and if the 'spare parts' are used up then in a repeat of the 1975 missions, the cost of a 1981 rover mission would be increased by the need to build the lander and orbiter as well as the rover.

Leaving aside these difficulties for the present, just what would be involved for a lander-orbiter-rover mission in a few years time? The basic rover design suggests a 238-pound vehicle, which would add a total weight of 282 pounds to the Viking lander, including stowage and deployment mechanisms. The Martin Marietta Corporation sees no serious problems in having this vehicle ride piggyback on top of the Viking lander and suggests that this would only involve a slight loss of the lander's other scientific capability. As things now stand, the scientific payload of the rover, including camera, spectrometer, X-ray diffractometer and other experiments, would be 89 pounds.

The total weight of the lander-rover package would be 1,583 pounds; this is 106 pounds more than specifications for the 1975 landers define as safe, but it turns out that the rocket motors of these landers exceed their specification and that the maximum safe weight for the lander-rover could therefore go

up to 1,644 pounds if need be.

As well as making its own investigations over a range of 45 km, such a rover could make itself useful by off loading instrument packages from the lander and carrying them several metres away from the landing point, so that they could be deployed more efficiently.

Since the cost of integrating the rover into the lander system, which could be as much as 25% of the total cost of the rover, would be borne by NASA, it seems that ESRO could make a great contribution to the unmanned exploration of the planets for a cost of about \$60 million. This seems a small price to pay and it is to be hoped that ESRO is indeed taking the project seriously.

Amateur and professional entomology

from a Correspondent

THE entomological *Bulletin of the British Museum (Natural History)* is a handsome production, as befits so old and eminent an institution. Its recent issues, comprising volume 28 parts 6 and 7, and volume 29 parts 1 and 2, as well as supplement 20, provide good samples of the sort of systematic work that goes on within the museum walls. There are two works by members of the museum's staff, two by entomologists from other institutions who have worked on the museum's collections, and one by an amateur lepidopterist to show that an ancient and very English tradition is still upheld. One work provides a list of the numerous type specimens of an important butterfly genus held by the museum, two provide revisions of the species of particular genera, drawing more or less extensively on materials from other museums as well as the British Museum. The two largest parts are concerned with higher level groupings, an aspect of classification which sometimes tends to be neglected in publications of this kind. The two, however, differ profoundly in nature.

C. M. F. von Hayek, of the museum's staff, provides "A Reclassification of the Subfamily Agrypninae (Coleoptera; Elateridae)" (*Bull. Br. Mus. nat. Hist. (Entomology)*, Suppl. 20, 1-309; 1973) and the amateur J. N. Eliot deals with "The Higher Classification of the Lycaenidae (Lepidoptera)" (*ibid.*, 28, 373-508; 1973). Hayek's work is in the best professional tradition; she provides a very full discussion of the complicated synonymy in the group, a clear and workable key to genera and full synonymic catalogues of the species for each genus, with the designation of numerous lectotypes, many of them in foreign museums. She eschews any consideration of larval characters (known for many of

the species she deals with), habits or phylogeny, and is not very generous with illustrations, as compared with the other four authors. Her most questionable classificatory decision is the inclusion in Agrypninae of the genus *Octocryptus*, about which she herself expresses reservations.

Eliot provides no catalogues of species or even of genera, but provides keys down to the level of tribes and sections (= subtribes), and numerous illustrations of male genitalia and wing scales, including six plates of electron micrographs. A large part of his space is taken up with the systematic, adaptive and phylogenetic significances of characters of his butterflies, and he provides an extensive account of their phylogeny, including a dendrogram. The speculative nature of much of this is admitted by Eliot, and it remains for specialists in the group to evaluate his theories. He takes account of larval and pupal characters, geographical distribution and palaeogeography, but pays little attention to food plants (Ehrlich and Raven's celebrated *Butterflies and Plants: a Study in Co-evolution* is not even cited in his bibliography). Eliot's paper is designed to evoke thought and curiosity about his lycaenid butterflies, a result which Hayek is not likely to achieve for the Agrypninae, for all the usefulness her work will have for those concerned with the identification and arrangement of museum collections of the group. On the other hand, one feels that Eliot's work might gain from some injection of Hayek's formal procedural rigour, as she would certainly gain from his amateur breadth of outlook and intellectual curiosity.

New IR telescope

Buried in NASA's budget for 1975 is a little-noticed item which holds particular interest for astronomers. NASA is planning to build a large infrared telescope on Mauna Kea in Hawaii, some 14,000 feet above sea level. With a 3-m dish, it will be the largest infrared telescope in the world.

The chief reason for building the telescope—and the reason it is in NASA's budget rather than in that of the National Science Foundation—is to use it to get information on Jupiter, Saturn and their satellites in time for the 1977 Mariner Jupiter-Saturn flyby missions. Temperature profiles of the moons of those planets will be helpful in targeting the spacecraft to take a look at the most interesting features. Ultimately, however, the instrument, which will cost about \$6 million, will be used for general infrared studies of both galactic and extragalactic objects.

Infectious C-type virus isolated from a baboon placenta

Raoul E. Benveniste, Michael M. Lieber, David M. Livingston, Charles J. Sherr,
& George J. Todaro

Viral Leukemia and Lymphoma Branch, National Cancer Institute, National Institutes of Health, Bethesda, Maryland 20014

Seymour S. Kalter

Division of Microbiology, Southwest Foundation for Research and Education, San Antonio, Texas 78284

A C-type virus ("M7") has been isolated from a specimen of baboon placenta cocultivated with various mammalian host cell lines. Nucleic acid hybridisation with a ³H-DNA transcript of the viral genome demonstrates that this virus is genetically different from previously studied mammalian C-type viruses, and suggests that M7 is an endogenous baboon virus.

C-TYPE RNA-containing viruses have been isolated from tissues and cell lines of various mammalian species¹, including mice²⁻⁴, rats⁵, hamsters⁶, guinea pigs⁷, domestic cats⁸, pigs^{1,9}, woolly monkeys¹⁰ and gibbons¹¹. Because of the known aetiological role of these viruses in the generation of vertebrate neoplasms¹², there have been extensive attempts to isolate infectious C-type viruses from other primates, including man. Recent electron microscopic evidence indicates that C-type viruses are present in the placentas of baboons¹³ and rhesus monkeys¹⁴, and, less frequently, human trophoblastic tissue¹⁵. We describe here the isolation and *in vitro* propagation of a typical C-type virus from a normal baboon placenta. Nucleic acid studies suggest an endogenous baboon origin for this virus isolate and demonstrate that it is distinct from known described mammalian C-type viruses, including two of presumed primate origin.

First trimester placental tissue was obtained by Caesarian section from an 11-yr-old multiparous baboon (*Papio cynocephalus*) from the colony maintained at the Southwest Foundation for Research and Education, San Antonio, Texas. This animal was imported to the United States from Africa in 1968 and had not been used previously for medical research. A portion of the placenta was removed for viro-

logical studies and the remainder was processed for nucleic acid extraction. Small pieces of the placenta were cocultivated directly with the indicator cell lines described in Table 1. In addition, a 5 g sample was homogenised in a Teflon pestle tissue grinder, suspended in 15 ml of cell culture medium, and centrifuged at 1,000g for 20 min. The supernatant was filtered through a 0.45 µm Millipore filter, and used to infect various mammalian cell lines, some of which are highly permissive for endogenous mouse and cat C-type viruses^{16,17}. The cultures were transferred every 2 weeks, and, in most cases, by the third transfer there was no evidence of baboon placental cells remaining in the cocultivated cultures.

Cultures were tested for C-type virus production by assaying for viral reverse transcriptase in the tissue culture media¹ (Table 1). After 5 weeks of cocultivation, C-type viral replication was first detected in FCf2Th, a foetal canine cell line. By 13 weeks, viral replication could also be detected in the rhesus monkey cell line, DBS-FRHL-1, in the bat lung cell line, Tb1Lu, and in the human rhabdomyosarcoma line, A204. Viral replication was also detected after 13 weeks in the cultures of A204, DBS-FRHL-1 and Tb1Lu which received filtered extracts of the baboon tissue (Table 1). The four other cell lines remained virus-negative during the 3-month test period.

The polymerase-positive foetal canine cell culture, FCf2Th, was examined by electron microscopy. As Fig. 1 shows, typical C-type viral particles were present in the extracellular space and in intracytoplasmic vacuoles, and were seen budding from the cell membranes. Designated M7, this virus rapidly generated productive infections of previously virus-free cultures of A204, DBS-FRHL-1, Tb1Lu, the mink cell line Mv1Lu, the dog cell line MDCK and the equine cell line E. Derm. No viral replication was detectable in rat NRK cells or in a foetal cat strain, FFc60WF,

TABLE 1 Growth of Baboon Placental Virus on Various Mammalian Cell Lines

Cell line (or strain)	Origin	Supernatant reverse transcriptase assay (c.p.m. × 10 ⁻³ , ³ H-TMP incorporated)					Days after infection with filtered extract	
		15	23	36	60	90	60	90
A204	Human rhabdomyosarcoma ²¹	0.9	3.5	10.0	20.7	749.8	764.3	810.0
A1215	Gibbon connective tissue	0.4	0.7	1.4	NT	1.8	1.1	NT
DBS-FRHL-1	Foetal rhesus lung ²²	2.6	3.2	1.7	33.8	1025.6	4.3	1080.2
FCf2Th	Foetal canine thymus (NBRL)	1.1	1.0	209.6	227.7	NT	NT	NT
SIRC	Rabbit cornea (ATCC)	0.6	0.6	2.7	5.6	2.9	3.9	5.3
Tb1Lu	Bat lung (ATCC)	0.8	0.6	1.5	4.5	762.6	4.0	337.0
FFc60WF	Foetal cat (NBRL)	1.6	1.5	1.5	3.3	2.3	NT	NT
Bu(IMR-31)	Buffalo lung (ATCC)	1.0	2.1	2.1	2.4	1.5	1.1	2.5

Cell culture medium was assayed at various times after cocultivation or infection for reverse transcriptase activity as previously described¹. Results are expressed as c.p.m. of ³H-TMP incorporated into poly(dT) product during a 60 min incubation at 37°C (40,000 c.p.m. minute is equivalent to 1 pmol of ³H-TMP). ATCC, American Type Culture Collection, Rockville, Maryland; NBRL, Naval Biomedical Research Laboratory, Oakland, California.

NT, not tested.

Fig. 1 Electron micrographs of C-type virions released by a foetal canine thymus cell line (FCf2Th) infected with an extract from a baboon placenta. Cell monolayers were fixed with buffered 2% glutaraldehyde and then scraped off with a rubber policeman. Cells were then sedimented and fixed in 1% buffered osmium tetroxide. After overnight incubation in cold 0.5% uranyl acetate, the cells were dehydrated and embedded in Epon. Thin sections were doubly stained in uranyl acetate and lead citrate and examined with a Siemens Elmiskop 1A electron microscope. A, intracellular particles. B and C, particles budding from the foetal canine cells. D, extracellular C-type particles. The scale represents 100 nm.

that is permissive for both feline leukaemia virus and endogenous feline C-type viruses (RD114/CCC group)¹⁶.

M7 virus was grown in FCf2Th cells, concentrated by continuous flow centrifugation, and further purified by isopycnic banding on sucrose gradients. The peak of reverse transcriptase activity occurs at a density of 1.16 g cm⁻³, characteristic of C-type viruses. Banded virus was disrupted with detergent and chromatographed on a Sephadex G-100 column calibrated with several protein markers. The reverse transcriptase activity eluted at a position corresponding to a molecular weight of 70,000, similar to that reported for other mammalian C-type viral polymerases¹⁸. Enzymatic activity assayed with a poly(A) template and oligo (dT)₁₂₋₁₈ primer showed the divalent cation preference for Mn²⁺ over Mg²⁺, characteristic of mammalian C-type viruses¹⁹.

The relatedness of the M7 virus to other C-type viruses was determined by comparing nucleic acid homology using DNA-RNA hybridisation. A single-stranded ³H-DNA copy of M7 viral RNA prepared using endogenous RNA-dependent DNA polymerase in the presence of actinomycin D²⁰ was annealed to viral RNAs or to cytoplasmic RNA extracted from cell lines that release C-type virus. Table 2 shows representative data obtained after digestion of the RNA-DNA hybrids with the single-strand specific nuclease,

S₁²⁰⁻²². The data have been normalised with respect to the final percentage saturation hybridisation values obtained with M7 viral RNA; these values ranged from 50-60%. Interpretation of RNA-DNA hybridisation using ³H-DNA prepared from an endogenous reverse transcriptase reaction is limited since the probe need not represent equally the entire viral RNA²³. Thus, homologies between infrequently transcribed portions of the M7 genome and other viral genomes may not be detected. Nevertheless, the data show that viral RNA extracted from three murine viruses, a rat virus, a feline virus, a Chinese hamster virus, a pig virus, and two presumed primate viruses (woolly monkey and gibbon) have less than 2.0% homology to the ³H-DNA probe prepared from M7. The probe hybridised to a small extent (10%) with an endogenous feline virus, RD114; the significance of this relationship is not yet clear. These data

TABLE 2 Nucleic Acid Homology of the M7 ³H-DNA Product to other C-type Viral RNAs

C-type virus	Origin	Percent M7 ³ H-DNA hybridised
M7	Baboon placenta	100.0
Gibbon	Gibbon lymphosarcoma	1.5
Woolly	Woolly monkey sarcoma	2.0
Feline	Cat leukaemia (Rickard)	1.8
	Human rhabdomyosarcoma cell line passaged through kittens (RD114)	10.0
Murine	Mouse leukaemia (Rauscher)	0.0
	Transformed mouse cell line (S16CL2)	0.5
	Human rhabdomyosarcoma cell line passaged through NIH Swiss mice (AT-124)	0.0
Chinese hamster	Hamster peritoneal cell line (B14-I50)	1.4
Rat	Rat thymus cell line (RT21c)	2.0
Porcine	Pig kidney cell line (PK-15)	0.0

Approximately 2000 c.p.m. (0.07 pmol of ³H-TMP incorporated into DNA) of a single-stranded M7 ³H-DNA product was hybridised to either viral or cytoplasmic RNA²⁰. The data shown represent the averages of final saturating percentage values obtained after adding increasing amounts of viral RNA (up to 20 µg) or cytoplasmic RNA (up to 2 mg) extracted from a virus-producing culture. The percentage hybridisation values have been normalized with respect to the final percentage hybridisation obtained with the homologous M7/FCf2Th RNA (actual values ranged from 50-60%). Hybridisation was carried out for 72 h at 41°C in the presence of 38% formamide as previously described²⁰. The formation of ³H-DNA-RNA hybrids was detected with S₁ nuclease²⁰⁻²². RNA extractions were performed as described previously^{20,23}. S16CL2, PK-15, B14-I50 and RT21c are endogenous viruses spontaneously released from their respective mouse, pig, Chinese hamster and rat cell lines. The Rickard strain of feline leukaemia virus was grown in a cat thymus cell line (F422), Rauscher murine leukaemia virus in the murine line JLSV-9, RD114 and AT-124 in a human rhabdomyosarcoma cell line (RD), gibbon and woolly monkey leukaemia viruses in the human rhabdomyosarcoma cell line (A204), and M7 in the foetal canine thymus cell line, FCf2Th. These viruses and their host cell lines have been described previously²⁴. Viral 70S RNA was extracted²⁵ from gibbon, woolly monkey, feline and murine viruses. The source of rat, porcine, Chinese hamster and M7 viral RNA was cytoplasmic RNA extracted from cultures producing these viruses. Both sources of RNA have been shown to yield similar data²³.

are also obtained when a reverse transcript prepared from each of the viruses listed in Table 2 is annealed to M7 viral RNA. Immunological studies of M7 viral reverse transcriptase and group-specific protein also demonstrate that the virus can be distinguished from known C-type virus isolates. These results argue against the possibility that the M7 isolate resulted from inadvertent infection of the animals, specimens or cell cultures by known laboratory C-type viruses.

To ascertain whether M7 could be an endogenous baboon virus, a single-stranded ³H-DNA copy of M7 RNA was

annealed to DNA extracted from a normal baboon liver. As Table 3 shows, the M7 probe hybridised fully to the DNA extracted from baboon liver and from the placenta from which the virus was isolated. Thus, sequences in the DNA of the liver and placenta from two baboons are completely homologous to those found in the M7 virus that was grown in dog cells. Tissues from four other baboons also contain DNA homologous to the M7 viral DNA probe (unpublished experiments). In contrast, DNA extracted from dog and pig liver, from a murine cell culture producing mouse C-type virus (S2CL3), and from the uninfected foetal canine cell line FCf2Th hybridised to less than 6% of the probe. There is a small amount of M7-related information in feline liver DNA (15%); the nature of this feline-baboon viral homology is examined in a separate report.

Cytoplasmic RNA extracted from the normal baboon liver and from the baboon placenta from which M7 was isolated was tested for its ability to anneal to the M7 ³H-DNA probe. Table 4 shows that whereas M7-specific viral RNA is readily detectable in baboon placenta, the addition of up to 0.9 mg of RNA from the baboon liver resulted in less than 2.6% hybridisation to the M7 probe. Thus, M7 viral information, though present in the cellular DNA, is not extensively transcribed in normal baboon liver tissue.

C-type viruses have been observed by electron microscopy in baboon placental tissue, and the hybridisation data demonstrate that RNA homologous to the M7 virus genome is being produced. In contrast, viruses have not been seen in adult baboon liver, and M7 viral RNA is not detectable by nucleic acid hybridisation. Thus, while viral genetic information is present in the DNA of both a virus-producing tissue (the placenta) and an apparently virus-free tissue (the liver) only the placental tissue is 'switched on' for virus production. The physiological basis for control of C-type virus expression and the mechanisms that allow virus activation in placental tissue remain to be elucidated.

These findings suggest that M7 is an endogenous C-type virus of the baboon. Similar nucleic acid hybridisation experiments have previously shown that chickens²⁴⁻²⁶, cats²⁷⁻²⁹ and pigs³⁰ also have vertically transmitted C-type viral genomes. Since ³H-DNA probes prepared from the woolly monkey virus and the gibbon ape virus show little or no homology to the DNA extracted from normal woolly or gibbon tissues (Scolnick *et al.*, manuscript submitted; Ben-

TABLE 3 Hybridisation of M7 ³H-DNA to DNA extracted from Tissues of Various Species

Species	Tissue	Percentage M7 ³ H-DNA hybridised
Baboon	Placenta	100.0
	Liver	115.0
Canine	Liver	5.0
	Cell culture (FCf2Th)	6.0
	Cell culture (FCf2Th)	100.0
	(M7 infected)	
Feline	Liver	15.0
Porcine	Liver	1.0
Murine	Cell culture (S2CL3)	2.0

The data show normalised percentage hybridisation values to the M7 ³H-DNA probe obtained after annealing to cell DNA to a *Cot* value of 8×10^3 (corrected for salt concentration to 0.12 M phosphate as described by Britten and Smith³⁴). DNA-DNA hybridisations were performed as previously described³⁰; the hybrids were detected with S₁ nuclease. DNA extractions were performed as described previously³⁰. The ratio of cell DNA (300 µg) to ³H-M7 DNA (0.1 ng) was 3×10^6 .

veniste *et al.*, manuscript submitted), M7 seems to be the first example of a vertically transmitted C-type virus of primates.

Our experiments demonstrate the validity of a general strategy for *in vitro* isolation of C-type viruses involving

cocultivation of suspected virus-producing tissues with cells from various species to maximise the probability of finding a permissive host. The same general approach may be applicable in attempts to isolate infectious C-type viruses from primates other than the baboon and from tissues other than the placenta.

TABLE 4 Expression of M7 Virus-specific RNA in Baboon Liver and Placental Tissue

Tissue	µg RNA added	Percentage M7 ³ H-DNA hybridised
Placenta	94	12.0
	282	22.5
	940	40.5
Liver	90	1.8
	450	2.6
	900	2.4

Approximately 1,600 c.p.m. of a single-stranded M7 ³H-DNA probe was hybridised to increasing concentrations of cytoplasmic RNA extracted from the baboon placenta from which M7 was isolated and from a normal liver of another baboon. The percentage hybridisation values have been normalised with respect to the final percentage hybridisation obtained with RNA extracted from the M7-infected foetal canine cell culture, FCf2Th; this value ranged from 50-60%. See legend to Table 2.

Dr A. Hellman helped in these studies; D. Stuart and M. Sturm prepared the electron micrographs. We thank R. Heinemann, C. Meade, C. Meyer and G. L. Wilson for help with the experiments. This work was supported in part by contracts from the National Institutes of Health Special Virus Cancer Program.

Three-dimensional structure of yeast phenylalanine transfer RNA at 3.0 Å resolution

F. L. Suddath, G. J. Quigley, A. McPherson, D. Sneden, J. J. Kim, S. H. Kim* & Alexander Rich

Department of Biology, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139 and *Department of Biochemistry, Duke University, Durham, North Carolina 27707

At 3 Å resolution, the electron density map of crystalline tRNA shows the polynucleotide chain as an alternating series of ribose and phosphate peaks. Bases are seen, especially in the double helical stem regions. A complete three-dimensional model of the L-shaped molecule has been built.

TRANSFER RNA is the molecule on which the polypeptide chain is assembled when tRNA interacts with mRNA. There is considerable interest in the three-dimensional structure of this molecule as a first step in understanding the detailed mechanism of protein synthesis. For several years we have been analysing crystals of yeast phenylalanine tRNA. The molecule crystallises in an orthorhombic unit cell ($P2_12_1$, $a = 33\text{Å}$, $b = 56\text{Å}$, $c = 161\text{Å}$) and these crystals produce high resolution X-ray diffraction patterns¹. We obtained heavy atom derivatives which made it possible to calculate an electron density map initially at a resolution of 5.5 Å² and at 4.0 Å resolution³. From the latter study it was possible to discern the overall shape of the molecule and show that the molecule was L-shaped with one arm of the L containing the CCA and TΨC stems while the other arm contained the dihydrouracil (hU) and anticodon stems which are components of the familiar cloverleaf arrangement of the polynucleotide sequence of yeast phenylalanine tRNA⁴ (Fig. 1). At 4 Å resolution the ribose-phosphate groups could be seen as individual peaks and the tracing of the chain was carried out largely by following adjacent peaks in the electron density map. Now we report that at 3 Å resolution the phosphate groups are typically seen as individual peaks separated from the ribose peaks. In addition, many of the purine and pyrimidine bases can be seen, especially in those regions in which base pairs are formed. The tracing of the polynucleotide chain seen at 3 Å resolution is virtually the same as that seen at 4 Å resolution, but many more details begin to emerge.

Structure and electron density

The experimental details for crystal growing and heavy atom derivative formation as well as data collection have been described previously^{1,2}. We have explored more fully

the conditions under which heavy atom derivatives can be formed and have developed several more heavy atoms sites, whose positions in the unit cell are listed in Table 1. The most important of these are the samarium and osmium derivatives. There are four samarium sites, two of which have major occupancies and two of which are less fully occupied. The osmium derivatives have in addition to the major site described previously², two sites with lesser occupancies. A double derivative has been obtained by soaking crystals initially with potassium osmate and then with samarium acetate. In addition, we have platinum de-

Fig. 1 The nucleotide sequence of yeast phenylalanine tRNA in the conventional cloverleaf diagram⁴. The nucleotides are numbered starting from the 5' end.

derivatives containing four sites and praseodymium derivatives with the same four sites as those found in the samarium derivatives.

The 3 Å sphere contains 6,807 unique reflections for this unit cell and of these, 4,902 were used in calculating the three-dimensional electron density map. Bijvoet pair data was collected for the derivatives. The overall figure of merit is 0.66 for the data used and the various residuals for each of the different derivatives are listed in Table 2. It can be seen that the most useful data was that produced by the samarium and osmium-samarium derivatives. The platinum data had only limited value and the osmium data was useful likewise only at low resolutions. A full crystallographic report will be published elsewhere.

Three-dimensional electron density maps were plotted at intervals of approximately 0.8 Å along the *a*, *b* and *c* axes. The map sections perpendicular to the *b* axis were used in assembling molecular models because of the more ready visualisation of the molecule. The electron density contours were drawn on glass or plastic sheets at a scale of 2 cm Å⁻¹ which were then mounted in a Richard's box⁵.

TABLE 1 Heavy atom parameters

	X	Y	Z	Occupancy*
Sm (3.0Å)	0.555	0.169	0.275	M
	0.279	0.373	0.232	M

* Occupancy: M, major site; I, intermediate site, W, weak site.

Kendrew wire models were used to build the molecule. The electron density map showed the gross outlines which were described previously in the 4 Å map. In addition, the 3 Å map revealed much more detail than was available at 4 Å. Substantial regions of the map are occupied primarily by solvent and there is very little accumulation of electron density in these areas. A channel of approximately 36 × 40 Å runs parallel to the *a* axis throughout the crystal and it permits the cell shrinking phenomena described earlier⁶. The double helical stems which were recognisable at 4 Å resolution now become clearly resolved; ribose and phosphate groups can be readily discerned from each other over most of the stem regions and the characteristic zigzag array of these two groups provide the continuity needed for tracing the backbone of the molecular chain. Figure 2 shows a photograph of a Kendrew wire molecular model built to fit the electron density in the map. In this view the anticodon is in the upper left and the CCA stem is in the upper right with the TΨC and hU loops forming the corner at the bottom. The L-shaped form of the molecule is readily apparent. The entire asymmetric unit is shown in this view with the exception of three terminal nucleotides CCA at the 3'OH end. The CCA end of one molecule extends into the neighbouring unit cell where it rests close to the anticodon stem of an adjacent molecule. It was not included in Fig. 2 to increase the clarity of the photograph. The distance

between the 3' hydroxyl group at one end of the L-shaped molecule and the anticodon bases at the other end of the L is 77 Å.

TABLE 2 Refinement statistics

	Sm	Os-Sm	Os	Pt	Pr
N	4843	3309	2773	1943	556
Resolution(Å)	3.0	3.0	4.0	4.0	5.0-4.0
R_K	0.094	0.110	0.194	0.310	0.087
R_M	0.63	0.73	1.18	2.52	0.74
R_W	0.49	0.68	1.53	7.76	0.72

N, number of reflections; the residual values R_K , R_M and R_W are defined in ref. 2.

Chain tracing

In attempting to trace the chain from the electron density map, several criteria and constraints were used. The first constraint is the fact that the polynucleotide backbone can be extended to a maximum repeat distance of approximately 7.5 Å or a minimum distance of approximately 4.5 Å. Second, the chain needs connectivity, that is, it should be traceable over its entire length without any gaps in the electron density map. Third, there must be a relationship between the total electron density in the map and the length of polynucleotide chain which is used to interpret the map. All or most of the high density regions in the map should be accounted for. Fourth, the polarity of the polynucleotide chain can be determined in double helical regions. This is due to the fact that these regions show both major and minor grooves in the electron density map. In interpreting these maps, we used conformational data from the fibre diffraction analysis of double helical RNA⁷ as well as from the recent single crystal analyses of fragments of RNA double helix^{8,9}. These studies provided models for interpreting the right-handed double helical stem segments and they unambiguously fix the direction of the polynucleotide chain.

In regions of the map which do not contain double helical segments, however, the connectivity and polarity of the chain is more difficult to determine. In these regions we try to recognise the base peaks and utilize conformational information obtained from the single crystal structure analysis of oligonucleotides⁸⁻¹¹. In addition, we have used the secondary structure implicit in the cloverleaf formation shown in Fig. 1

Fig. 2 A photograph of a Kendrew wire model of yeast phenylalanine tRNA based on the 3 Å resolution electron density map. The model is built at a scale of 2 cm Å⁻¹. The CCA stem is at the upper right. The TΨC and hU loops are at the bottom and the anticodon loop is at the upper left. The L shape of the molecule is evident.

R374

Pars. One 317v Library

as an adjunct for the chain tracing. Although the map contains double helical stem regions in which the chain tracing is unambiguous, there are areas in which the chain tracing is less clear. In particular, the TVC and hU loop areas are close together near the corner of the L and both chains follow a fairly irregular course. Furthermore, there are additional peaks which we interpret as tightly bound cations. This makes the chain tracing in these areas much less certain than in the double helical stem regions.

As mentioned above the three nucleotides CCA at the 3'OH end of the molecule extend out from the CCA stem and are adjacent to the anticodon stem of a neighbouring molecule. The electron density peaks are slightly lower in the CCA region of the molecule than elsewhere, suggesting somewhat greater disorder in that part of the molecule. The 3' terminal ribose peak is found 3 Å from the major osmium site, in agreement with our suggestion that this site may be due to the formation of an osmium-bipyridine complex with the two *cis* hydroxyl groups of the 3' ribose³. But as we have found two additional osmium sites, it is clear that this is not the sole mechanism by which osmium can complex to RNA molecules. In this regard it is likely that the osmium derivative reported by Schevitz *et al.*¹² represents an alternative mode of complexing.

The three-dimensional Kendrew model was built first by assembling the double helical segments while paying attention to the geometry of these segments as discussed above. A very long double helical segment containing approximately one turn of the helix is seen at one end of the molecule (right side of Fig. 2), the 3' end of which is attached to the isolated segment of four nucleotides which we interpret as the ACCA end. Once the double helical stem segments were built, the identification of loops was guided by the cloverleaf diagram. In general, we are reasonably confident about the assignment of residues in the double helical stem segments. We are not as confident of the loop areas, however, since there are often ambiguities regarding continuity where there are many close contacts.

Figures 3, 4 and 5 show three sections of the electron density map perpendicular to the *a*, *b* and *c* axes. These maps are presented to illustrate the kind of resolution seen in the electron density map, and at the same time the superimposed heavy black lines illustrate our interpretation of those regions of the map. Figure 3 shows a slice, perpendicular to the *c* axis, which passes through one strand of the anticodon stem. It can be seen that there is a reasonable resolution of ribose and phosphate peaks and two of the base pairs in the stem region lie almost in the plane of this slice. Although the base pair can be seen in the map, it is clear that we cannot differentiate one base from another at this resolution. There are sections of electron density in the upper right and lower right of Fig. 3 which arise from neighbouring molecules.

A section perpendicular to the *b* axis is shown in Fig. 4. The large empty area to the left is the region filled largely by solvent and it is this region which disappears when the crystals are transformed into a smaller unit cell by shrinkage⁶. This section contains an elongated length of polynucleotide chain including part of the hU stem region. The zigzag nature of the ribose phosphate chain can be seen fairly clearly. The vertical *a* direction contains one and a half unit cells because the molecule itself spans more than one unit cell in the *a* direction. All the labelled residues in Fig. 4 are in one molecule. The unlabelled parts are related to the labelled parts by symmetry, either a translation in the vertical *a* direction or a two-fold rotation as indicated by the axes shown in the figure. The peak labelled M is interpreted as a metal ion which is found in the position where two molecules are in close contact.

Figure 5 shows a section perpendicular to the *a* axis. The

arc of electron density seen at the left of the figure is a portion of the TVC stem which lies in the *bc* plane. The section at the far right cuts through the anticodon part of the molecule one unit cell below whereas the portion in the middle which contains very little electron density lies between two molecules.

Fig. 3 A composite of electron density map sections cut perpendicular to the *c* axis in the interval $z = 0.110-0.120$. The vertical distance is slightly greater than an *a* axis repeat of 33 Å. The horizontal axis is close to one half of the 56 Å *b* axis. The heavy lines represent portions of the molecule, and a part of the anticodon stem is seen. The electron density at the upper right and lower right arise from adjacent molecules in the next unit cell. P, phosphate group; R, ribose.

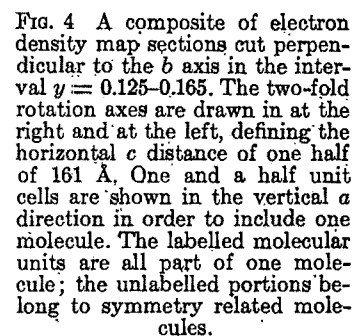

As is obvious from Figs 3, 4 and 5 most of the peaks of electron density are accounted for by structural features of the molecule. Some peaks, however, are not accounted for by the polynucleotide backbone. Many of these are believed to be ions, especially since a number of them are found within 4 Å of the negatively charged phosphate groups. In addition to the magnesium ions, the solvent also has the arsenic-containing cacodylate ions of the buffer as well as the polycationic spermine. Some additional experiments are necessary in order to ascertain the nature of these additional peaks in the electron density map.

Molecular structure

There are a few important features of the connections between the stem areas that should be described. In going from the CCA stem to the hU stem there are two nucleotides, 8 and 9, where the chain makes an abrupt change in direction. The uracil in position 8 was found to be partially stacking over the cytosine of nucleotide 13; thus the photodimerisation reported by Yaniv *et al.*¹³ can easily be explained by this juxtaposition. We have made a reasonable tracing of the hU loop in which the guanine of nucleotide 15 forms a hydrogen bonded pair with the cytosine of nucleotide 48. This base pair has been described as a possible feature of the secondary structure of tRNA¹⁴. However, since this occurs in a loop region, we must still regard this as somewhat tentative.

The electron density in the CCA stem shows only a slight irregularity in the region of the guanine-uracil base pair; thus we can say that these bases are not folded out of the stem, but rather are found stacked within the double helical portion of the molecule. Further work, however, is needed to show whether or not these bases are hydrogen bonded in the stem.

The diffraction pattern of this orthorhombic unit cell extends out to a resolution of 2.3\AA , thus almost twice as

much diffraction data can be collected by extending the study from 3Å to 2.3Å. We are continuing the analysis in this direction and are also continuing the search for additional heavy atom derivatives which will help to define further the phases used in calculating the three-dimensional electron density map. At present we are confident of the overall form of the molecule and can define in reasonable detail the

double helical stem regions. The loop areas, however, remain somewhat uncertain and although we can make quite reasonable chain tracings we cannot be certain that these chain tracings are unique. This is of particular importance in that we would like to define completely the conformation of the hU loop as well as the detailed and interesting interaction between the T Ψ C and hU loop areas in the corner of the molecule. We hope that these will emerge in our continuing study.

This research was supported by grants from National Institutes of Health, the US National Science Foundation, NASA and the American Cancer Society, and by a Medical Foundation fellowship to G.J.Q. and an NIH training grant award to D.S. We thank Paul Blattmann, Joel Sussman, Jesse Pittard, Susan Bock and Virginia Scarlett for assistance.

Morphine-like drugs inhibit the stimulation by E prostaglandins of cyclic AMP formation by rat brain homogenate

H. O. J. Collier & A. C. Roy

Miles Laboratories Limited, Stoke Poges, Slough SL2, 4LY, Buckinghamshire

In homogenate of rat brain, morphine, at concentrations obtainable in vivo, inhibited the stimulation by prostaglandin E₁ or E₂ of cyclic AMP formation, without inhibiting the basal production of cyclic AMP. Heroin was more and methadone less active than morphine, whereas dextrorphan was inactive and naloxone antagonised the effect of morphine. This inhibition may represent a mechanism whereby morphine-like drugs exert their analgesic or other effects.

EXPERIMENTAL administration of E prostaglandins elicits the main pharmacological effects: pain or hyperalgesia^{1,2,3}, diarrhoea^{4,5} and cough^{6,7}, that opiates are clinically used to lessen⁸. This antithesis extends to other effects of E prostaglandins and opiates⁹⁻¹³. Reports have also appeared of antagonism between morphine and E prostaglandins in some isolated intestinal preparations¹⁴⁻¹⁷ and in the release of adrenocorticotrophic hormone^{18,19}. Such considerations led us to examine whether morphine might inhibit some biochemical process of E prostaglandin (PGE) production or action at appropriate concentrations *in vitro*. The finding of Vane²⁰ that morphine does not inhibit biosynthesis of PGE₂ was confirmed, using rat brain homogenate with glutathione and hydroquinone as cofactors (S. A. Saeed, P. J. Gardiner and H. O. J. C., unpublished). Rat brain homogenate, however, converts adenosine triphosphate (ATP) to cyclic 3',5'-adenosine monophosphate (cyclic AMP) through the action

of adenylyl cyclase. We report that PGE₁ or PGE₂, but not PGF_{2 α} , stimulated the formation of cyclic AMP from ATP in rat brain homogenate and that morphine-like drugs potentially inhibited this stimulation without inhibiting the basal production of cyclic AMP in the absence of E prostaglandin.

Measurement of cyclic AMP formation

In preparing brain homogenate, Tris-HCl buffer (50 mM, pH 7.4), containing 250 mM sucrose, 1 mM MgCl₂, 25 mM KCl, 25 mM NaCl, 0.1 mM EDTA and 1.3 mM 2-mercaptoethanol, was used. The buffer was chilled to 0-2° C and operations were done whenever possible at this temperature. Rats (90-120 g) were decapitated, the whole brain was quickly removed, washed in buffer and transferred to fresh buffer. The brain was chopped and then gently homogenised in ten volumes of buffer in a Jencon glass homogeniser.

The formation of radioactive cyclic AMP from its labelled precursor, ³H-ATP, was measured at a total concentration of ATP in the reaction mixture of 1.16 μ M. An excess of non-radioactive cyclic AMP was included in the reaction mixture to protect the newly formed radioactive cyclic AMP from degradation by phosphodiesterase²¹. Brain homogenate (0.05 ml) was incubated with 0.75 ml of a mixture containing Tris-HCl (pH 7.4, 50 mM); MgCl₂, 2 mM; KCl, 10 mM; NaCl, 10 mM; bovine serum albumin, 0.015%; cyclic AMP, 3 mM; ³H-ATP (21 Ci mmol⁻¹), 2.5 μ Ci;

unlabelled ATP, 1 μ M; with or without E prostaglandin (0.25–50 μ g per tube) and drug at concentrations stated in the text. The drugs used were (–)morphine sulphate, (–)heroin hydrochloride, (\pm)methadone hydrochloride, dextrorphan tartrate and (–)naloxone hydrochloride, the concentrations of drug being expressed as active base. Incubations were carried out in duplicate at 30° C for 20 min in a Gallenkamp shaking incubator and were terminated by immersion in boiling water for 3 min after the addition of 2 mM cyclic AMP and 2 mM ATP. After freezing and thawing, the tubes were centrifuged for 15 min at 2,500g. Reaction blanks consisted of incubation tubes containing previously boiled supernatant fractions.

The labelled cyclic AMP formed was isolated by chromatography on Dowex 50W-X4 columns followed by a double Ba(OH)₂-ZnSO₄ precipitation²², care being taken that the pH of the final supernatants did not exceed 8 (ref. 23). The radioactivity contained in 1 ml aliquot of the final supernatants was measured in a Beckman LS-150 liquid scintillation spectrometer.

Blockade of PGE stimulation

In five experiments, addition of PGE₁ (50 or 25 μ g per 0.8 ml tube of incubate) increased cyclic AMP formation by 1.4–2.7 times the basal production in the control tubes (without added prostaglandin). In one experiment, PGE₁ was added to incubation tubes in amounts that were reduced tenfold. The stimulation by PGE₁ of cyclic AMP formation over that in control tubes was: 25 μ g PGE₁, 2.7 \times ; 2.5 μ g PGE₁, 1.2 \times ; 0.25 μ g PGE₁, 0.92 \times . In both of two experiments, PGE₁ was about equal to PGE₂ in stimulant activity. In one experiment in which PGE₂ was tested at 25 μ g per tube, this prostaglandin was inactive.

In five of five experiments, morphine inhibited the stimulation by PGE₁ of cyclic AMP formation by rat brain homogenate, without inhibiting the basal production of cyclic AMP (Fig. 1). The potency of morphine was high and dose-related. For example, in the experiment of Fig. 1, the 50% inhibitory concentration (IC₅₀) was 1.46 μ g ml⁻¹ (95% fiducial limits, 1.20–1.82) and the slope of the dose/response line based on percentage reduction of responses to PGE₁ per log₁₀ concentration of morphine was 61.90 with s. e. \pm 2.8. This slope was highly significant ($P < 0.001$). In another experiment, in which PGE₂ was used instead of PGE₁, morphine showed activity comparable with that against PGE₁ (IC₅₀, 2.03 μ g ml⁻¹).

When the amount of PGE₁ used to stimulate cyclic AMP formation was reduced ten-fold, from 25 or 50 to 2.5 or 5 μ g per tube, the effectiveness of morphine was raised (Fig. 2). In this figure, based on two experiments, the mean slope of the line relating the inhibitory effect of a given concentration of morphine (0.57 μ g ml⁻¹) to the log₁₀ concentration of PGE₁ was -16.26 ± 3.71 , which was highly significant ($P < 0.005$).

In one experiment, 8 mM theophylline was added to the incubation mixture. In this experiment, stimulation by PGE₁ of cyclic AMP formation, which was 2.6 times that in the control, was within the usual range and morphine was effective in a dose-related way at the usual concentrations (0.57 and 5.7 μ g ml⁻¹).

Heroin and methadone likewise inhibited the stimulation by PGE₁ of cyclic AMP formation by rat brain homogenate. In the experiment of Fig. 3, the IC₅₀ values in μ g ml⁻¹ were: heroin, 0.159 (limits 0.037–0.314); methadone, 10.6 (limits 6.53–21.8). The slopes of the dose/response lines, derived as for morphine, with standard errors, were: heroin, 49.57 ± 9.957 ($P < 0.02$); methadone, 69.62 ± 7.38 ($P < 0.005$). Neither slope differed significantly from that of morphine in Fig. 1. In two experiments, dextrorphan, at 50 or 600 μ g ml⁻¹, was devoid of inhibitory activity.

Fig. 1 Inhibition by morphine of the conversion of ³H-ATP to ³H-cyclic AMP stimulated by prostaglandin E₁ in rat brain homogenate. The amount of ³H-cyclic AMP formed after incubation for 20 min, in the presence or absence of 25 μ g per tube of PGE₁ and various concentrations of morphine, is expressed in mean c.p.m. \pm s.e.

We also tested whether naloxone antagonised the inhibitory effect of morphine on the stimulation by PGE₁ or PGE₂ of cyclic AMP formation. In both of two experiments, naloxone, at a molar ratio to morphine of 1:2, completely antagonised the effect of morphine. A feature of these experiments that will require further investigation was that naloxone alone also affected cyclic AMP formation.

In two preliminary experiments, using an analogous method, morphine also inhibited the stimulation by PGE₁ of cyclic AMP formation by homogenate of rat intestine. The IC₅₀ was roughly 2 μ g ml⁻¹.

Biochemical action and pharmacological effects

The stimulation by PGE₁ or PGE₂ of cyclic AMP formation by rat brain homogenate was probably due to the activation of an adenylyl cyclase; but, conceivably, it could have been due to inhibition of phosphodiesterase or of ATPase^{24,25}. That this effect of PGE₁ occurred in the presence of theophylline seems to rule out phosphodiesterase inhibition. Although the possibility that the effect was due to inhibition of ATPase seems slight and the activation of adenylyl cyclase by E prostaglandins is well documented, we prefer at this stage to speak of the stimulation of cyclic AMP formation rather than of adenylyl cyclase.

There seems little doubt that the interaction of E prostaglandins with the cyclic AMP system is a step in their mechanism of action in some cells. The above observations therefore raise the question: would inhibition of the stimulation by E prostaglandin of cyclic AMP formation in appropriate cells explain the mechanism of analgesic or other action of opiates? There are four lines of evidence bearing upon this question.

One line of evidence concerns the question of whether the occurrence and actions of E prostaglandins are such that their inhibition might explain some of the pharmacological effects of morphine. One such action of E prostaglandins is produc-

tion of pain or hyperalgesia; but this has so far been clearly demonstrated only in peripheral sites¹⁻³, whereas morphine is believed to act centrally²⁶⁻²⁸. There is some evidence, however, that in appropriate regions of the brain, E prostaglandins may also elicit pain or hyperalgesia. Thus, fever in which E prostaglandin is produced in the hypothalamus⁹, may be accompanied by severe headache or malaise. Again, in the rat, sodium salicylate, which inhibits E prostaglandin synthesis²⁰, lessens nociception generated by stimulation of the lateral hypothalamus with implanted electrodes²⁹. The mechanism whereby E prostaglandins might elicit or enhance pain centrally is uncertain; but they antagonise release or action of noradrenaline³⁰⁻³², which may exert an analgesic action³³⁻³⁵, and they may participate in acetylcholine release from nerve terminals¹⁷ and in conduction between neurones³⁶.

Because PGE₁ is thought to be "an ideal general mediator for raising body temperature"¹⁰, morphine might be expected to lower body temperature when this was being raised by production of E prostaglandins in the thermo-regulatory centres of the anterior hypothalamus. Morphine seems seldom to have been critically tested as an antipyretic while this mechanism was active; but we have traced one report in which this may have been done. In rats kept in a cold environment (5° C), injection of morphine, either 50 µg into the anterior hypothalamus or 50 mg kg⁻¹ intraperitoneally, did indeed lower body temperature, by a mean of 5-6° C (ref. 37). Whereas, when rats were maintained at 32° C, and PGE production in the thermoregulatory centres was presumably in abeyance, morphine by either route raised mean body temperature, by 1-2° C. In a thermoneutral environment (24° C) morphine had little effect in these experiments; but other investigators have found it to be mainly hypothermic when injected intracerebrally or systemically in the rat¹³. Tolerance can develop quickly to this hypothermic effect of morphine, revealing a hyperthermic component.

FIG. 2 Increased inhibition by morphine of the stimulation of cyclic AMP formation when the concentration of PGE₁ was reduced tenfold. The inhibitory effects in two experiments of one concentration of morphine (0.57 µg ml⁻¹), on the response to PGE₁ of rat brain homogenate are plotted against log concentration of prostaglandin.

Blockade of E prostaglandin in intestinal tissue might suppress diarrhoea, because E prostaglandin, which seems, with cyclic AMP to be involved in diarrhoea induced by ionising radiation³⁸ or toxins^{39,40}, increased fluid accumulation in the intestinal lumen^{4,5}.

A second line of evidence concerns antagonism between morphine, on the one hand, and cyclic AMP or PGE, on the other. If morphine acted as an analgesic by inhibiting PGE-activated cyclic AMP formation, we might expect that its potency would be reduced by administration of cyclic AMP. That cyclic AMP does indeed lessen the antinociceptive effect of morphine in the mouse and rat has been demonstrated⁴¹. There is evidence also that morphine can antagonise some effects of E prostaglandins on intestinal muscle¹⁵⁻¹⁷ and on the hypothalamus^{18,19}; and it has recently been proposed that morphine antagonises the mediation by E prostaglandins of acetylcholine release from guinea pig ileum¹⁷.

A third line of evidence is provided by our finding that the effectiveness of heroin, morphine and methadone, the ineffectiveness of the inactive stereoisomer, dextrorphan, and the antagonism of morphine by naloxone form a pattern consistent with the known pharmacological relationships of these drugs. Why the relative potencies of heroin, morphine and methadone against stimulation by PGE₁ of cyclic AMP formation slightly differ from their relative antinociceptive potencies *in vivo* could be explained in terms of the absorption and metabolism of these drugs, as discussed below.

Fourth, there is the question of how far the concentrations of opiates that inhibit the PGE stimulation of cyclic AMP formation *in vitro* correspond with those needed in tissues for antinociceptive effects *in vivo*. The antinociceptive ED₅₀ values of morphine obtained in the rat were 0.87 mg kg⁻¹ subcutaneously in the abdominal constriction test and 6.08 mg kg⁻¹ subcutaneously in the tail-pressure test⁴². After 5 mg kg⁻¹ morphine subcutaneously, values of 0.25 µg g⁻¹ and of 0.179 µg g⁻¹ were obtained for whole brain and 0.58 µg g⁻¹ for the hypothalamic area^{43,44}. In the experiment in Fig. 1, the IC₅₀ value of morphine for inhibiting the stimulation by PGE₁ of cyclic AMP formation in brain homogenate was 1.46 µg ml⁻¹. This, therefore, does not much exceed the value obtained for the hypothalamic concentration *in vivo* after a dose of the approximate ED₅₀ of morphine in the tail-pressure test. That morphine was more effective *in vitro* when less PGE₁ was used to stimulate cyclic AMP formation allows flexibility in matching *in vitro* and *in vivo* concentrations. Further flexibility could arise from the possibility that the drugs used might undergo some metabolism by rat brain homogenate *in vitro*.

Heroin is about three times as potent as morphine in the abdominal constriction test in the mouse⁴⁵, but its true analgesic potency is masked by its rapid conversion in the body to morphine and 6-monoacetylmorphine⁴⁶. In the guinea pig isolated ileum, heroin was about twice as active as morphine in a test that correlates well with analgesic activity⁴⁷. In antinociceptive tests in mouse, rat and rabbit, methadone is slightly more potent than morphine, but methadone is much better absorbed into the brain⁴⁸. In the rabbit, for example, to provide an equal antinociceptive effect, a concentration of methadone approximately thirty times higher than that of morphine is needed in the brain²⁸. The concentrations of heroin, morphine and methadone that inhibit the stimulation by PGE₁ of cyclic AMP formation *in vitro* thus probably correspond with the concentrations of drug or active derivative that are effective *in vivo*. Moreover, the relative potencies of (—) morphine and (±) methadone and the ineffectiveness of dextrorphan are consistent with their affinities for the opiate receptor of rat brain homogenate⁴⁸.

Thus, four lines of evidence support this analysis of opiate action. First, some actions of E prostaglandins are such that their antagonism would explain some of the main

pharmacological effects of opiates. Second, cyclic AMP antagonises the antinociceptive effect of morphine and morphine antagonises some effects of E prostaglandins. Third, the relationship between heroin, morphine, methadone, dextrorphan and naloxone in our experiments *in vitro* largely corresponds with their pharmacological relationship

FIG. 3 Inhibition by heroin (●), morphine (□) and methadone (○) of the stimulation by PGE_1 of cyclic AMP formation in rat brain homogenate.

in vivo. Fourth, the concentrations at which heroin, morphine and methadone inhibit PGE_1 *in vitro* roughly correspond with effective concentrations in brain *in vivo*. We therefore propose that the ability of opiates to inhibit the stimulation by E prostaglandins of cyclic AMP formation in rat brain homogenate, presumably by inhibiting stimulation of a neuronal adenylyl cyclase, represents a biochemical mechanism that could account for the analgesic and allied effects of these drugs. Such a mechanism could accommodate interactions of opiates with other humoral messengers: If this is how opiates act, then tolerance and dependence, which arise from the agonist action of opiates⁴⁹, are enhanced by cyclic AMP⁵⁰ and are partly blocked by indomethacin⁵¹, may represent a compensating hypertrophy of a part of the inhibited PGE-cyclic AMP mechanism.

We thank Mr N. M. Butt for technical and Mr L. C. Dinneen for statistical help, Professor M. Ginsburg for dextrorphan and Sankyo Ltd for naloxone.

Possible observation of tachyons associated with extensive air showers

SEVERAL searches¹⁻⁴ have been made for tachyons using either laboratory particle sources or high energy cosmic rays. Effects associated with their supposed characteristic mass and velocity have been searched for but so far no positive evidence has been reported. As has been repeatedly pointed out, however, the goal of these searches is so important that all possible avenues should be fully investigated. We report here apparently positive results from a pilot search for tachyons associated with cosmic ray showers of energy about 2×10^{15} eV.

The first interaction of a primary cosmic-ray nucleon occurs at a typical altitude of 20 km (ref. 5). Further interactions result in a cascade of relativistic particles travelling with speeds close to that of light (c). Thus, most of the particles in this extensive air shower (EAS) arrive at sea level with a time spread of only a few nanoseconds⁶. If any shower particles are produced with velocities greater than c , they should be observable in the time interval up to 20 km/ c (60 μ s) before the arrival of the shower front. The precise time depends on their velocity and production altitude. A pilot experiment has been conducted to search for particles arriving within this time period. In this experiment, the EAS which were studied had energies some two orders of magnitude higher than in previously reported work⁴.

A plastic scintillator was used to detect the particles. It is not clear what interactions a tachyon might have with the atmosphere or the scintillator. The present search was made assuming that tachyons are produced in EAS interactions at heights between 20 km and 400 m (800 kg m⁻² and 10,000 kg m⁻²) and have a sufficiently long absorption length for some to reach the detector. Detection might be accomplished by direct interaction of the tachyons with the scintillator or through the production of secondary particles which interact with the detector. It is not necessary that a single tachyon should produce a large response in the scintillator (as, for instance, a charged relativistic particle would). In principle, provided that observations are initiated by the detection of EAS, it is possible to sum results from many observations so that small non-random effects can be observed.

The chief experimental difficulty with this procedure is that if a recording device is triggered by the arrival of an EAS, it will be too late to observe the tachyon unless substantial signal delays are inserted. This was overcome in the present case by the use of a digital transient recorder (Biomation International, Palo Alto, California; model 610B) which enabled us to trigger our recording system from an EAS and then examine the signal from the particle detector recorded prior to the arrival of the trigger. The device continually samples and digitises (to six bit accuracy) the output of the particle detector. Two hundred and fifty-six words of this digitised data are stored in a shift register which is continually updated. Thus, when a trigger is received, the previous 256 words of data are in store (in our case representing 128 μ s) and can be output at leisure. Output was to a chart recorder after digital to analogue conversion. In this mode, the recorder only outputs 228 words (114 μ s).

The EAS trigger was obtained from the fast timing part of the air shower array at the Buckland Park field station of the University of Adelaide. Five 1 m square plastic scintillators, 50 mm thick, were used, in a square array of side 30 m, one scintillator being at each corner with one at the centre. Each scintillator was viewed with a Philips XP1040 photomultiplier and the arrival of an EAS was detected by a coincidence between the centre detector and any three of the outer detectors with a resolving time of 150 ns. Thus, air showers were detected from a cone about the zenith, with half angle of about 35°. The mean rate of showers was one per 500 s, corresponding to a minimum shower energy of about 2×10^{15} eV. In addition, one of the corner scintillators was also viewed by an RCA 8055 photomultiplier connected to a charge sensitive preamplifier, the output of which was the signal recorded by the transient recorder. The impulse response of the system had a width of 1.7 μ s at half maximum ensuring that a sampling interval of 0.5 μ s gave an acceptable reconstruction of the waveform on digital to analogue conversion.

Data from a total of 1,307 air showers, detected between February and August, 1973, have been analysed. The aim of the analysis was to demonstrate whether or not non-random effects were observable immediately preceding an EAS and for this reason a simple analysis procedure was employed. The time (with respect to the arrival of each EAS) of the largest excursion of the amplified photomultiplier output was noted. If there was doubt as to which of a number of pulses was the largest, all the apparently equal pulses were included. In practice, approximately 4% of the events had their two largest pulses sufficiently close in amplitude to cause ambiguity. In order to check on observer bias in assigning relative pulse heights, approximately 600 events were re-read by an independent chart reader. Some 3% of the events had the assignment of the largest pulse changed but no systematic bias was found.

The position of the shower front on the output trace can be adjusted; thus the time interval available for analysis is dependent on the exact setting of the transient recorder. For 1,176 of the events the record extended beyond 105 μ s before the air shower arrival. Figure 1a shows a histogram of the positions of the largest pulses for these events. The figure suggests that the distribution of the largest pulses is not uniform and a χ^2 test on the data indicates that there is only 1% chance that the data is from a uniform distribution.

In order to include data from all 1,307 recorded events it is necessary to limit the period of analysis to 97.5 μ s before the shower arrival. The resulting histogram is shown in Fig. 1b. A χ^2 test on this data shows less than 0.1% probability that the data is from a uniform distribution. In addition, since if tachyons are observed one might expect their arrival times to be spread over more than one 7.5 μ s bin, one can also test to see whether there are specific time regions contributing excessively to the non uniformity or whether the large χ^2 is due to a more or less random time distribution of excesses. This problem has been discussed by David⁷ who noted that a calculation of χ^2 involved the squaring of deviations from a hypothetical set and that independent information on the sign of the deviations was ignored. An examination of the distribution of bins above and below the mean shows that the probability that our data are selected from a uniform distribution is less than 1%, on the basis of a non-parametric run test.

The data were obtained in 12 runs containing between 70 and 180 events each and the data were tested for the possibility of non-random variations between runs. This was done

FIG. 1 The time distribution of largest photomultiplier pulse in the period prior to the arrival of an extensive air shower; *a*, data from 1,176 air showers in 14 bins of width 7.5 μ s; *b*, data from all 1,307 showers observed in 13 bins of width 7.5 μ s.

by comparing data obtained from individual runs with the final distribution. Taking deviations of each bin of each run from the normalised final distribution gave a χ^2 indicating less than a 10% probability that the individual runs were not

FIG. 2 The time distribution of largest photomultiplier pulses in 1,839 random samples of output in 13 bins of width 7.5 μ s.

randomly selected subsets of the total data.

The experiment has the unique quality that spurious pickup in the electronics is most unlikely to affect the result since pickup must occur at or after the arrival of the shower front, thus arriving after recording and storage of the data. It is arguable that the arrival of an air shower could generate interference in the recorder memory. If this were so, unless

FIG. 3 The time distribution of largest photomultiplier pulses in the 105 μ s period prior to 978 extensive air showers. The data was recorded at half the sampling rate of that in Figs 1 and 2 and analysed into 7 bins of width 15 μ s.

only the least significant bit were affected, a discontinuity in the trace would be expected after digital to analogue conversion. In more than 3,000 events no such effect was observed. In addition, grossly overloading the input amplifier with a pulse was found to have no effect on stored data.

In case there was some other form of pickup or of observer bias, we have triggered our coincidence system with artificial pulses and repeated the analysis on an apparently random sample of photomultiplier output; 1839 events were analysed in the same way as the air shower triggered data indicating on the basis of a χ^2 test a probability of about 40% that these test results were from a uniform distribution. The data are presented in Fig. 2. The probability that this test data and the EAS data are from the same distribution is less than one in 10^4 on the basis of a χ^2 test.

We have also operated our transient recorder at one half the previous sampling rate (with a lower bandwidth) and taken results over a similar range to that described above. These data from a further 972 showers were analysed into seven coarser bins (15 μ s wide) but otherwise a similar analysis technique was employed. The resulting distribution shown in Fig. 3 seems to exhibit the same broad features as Fig. 1. We use this as further evidence that the equipment and analysis technique are largely free from bias since the equipment was now operated in a rather different manner.

Ramana Murthy⁴ has reported an unsuccessful search for tachyons in EAS. Two detection techniques were employed, in one of which a liquid scintillator was used and a search made for particles immediately prior to EAS. This experiment is rather similar to the one described above but differs in a number of important respects. In order to avoid the use of long analogue delays, his measurements were initiated by the detection of single charged particles and a search was made for EAS following within 19.2 μ s. This technique is much less efficient than ours since only 1 in 250 potential tachyons was followed by an EAS within the time of interest. Also, potential tachyons have the additional constraint that

they must produce a response in the scintillator comparable with that produced by a conventional charged particle. As mentioned earlier, the EAS studied by Ramana Murthy were almost two orders of magnitude less energetic than those used by us and also a much smaller time range was examined. Since the peak in our distribution occurs after the 18 μ s time interval investigated by Ramana Murthy, the results cannot be directly compared. But a statistical examination of his published data using David's technique indicates that there is less than 5% probability that the data is from a uniform distribution. We note that, subjectively, the observed distribution seems to rise in the period prior to 13 μ s before the shower arrival. This is not inconsistent with our observations.

It is possible that an explanation may be found for these results without invoking the existence of tachyons. A. G. Gregory has pointed out to us that fission or spallation in the interstellar medium or production of associated particles at the source might account for the correlated arrival of cosmic rays. We note, however, that unless particles are produced with closely similar rigidity and velocity vectors they are unlikely to remain associated for long in the interstellar or source magnetic fields. A closely related problem has been discussed by Weekes⁸ in connection with pulsar periodicities in cosmic-ray arrival times.

We conclude that we have observed non-random events preceding the arrival of an extensive air shower. Being unable to explain this result in a more conventional manner, we suggest that this is the result of a particle travelling with an apparent velocity greater than that of light.

We thank Dr A. G. Gregory and Professors C. A. Hurst and J. R. Prescott for comments, Mr K. W. Morris for advice on statistical analysis, and Ms J. M. Taylor for chart reading. One of us (R.W.C.) holds a Queen Elizabeth Fellowship. The University of Calgary is thanked for the loan of equipment.

Black hole explosions?

QUANTUM gravitational effects are usually ignored in calculations of the formation and evolution of black holes. The justification for this is that the radius of curvature of space-time outside the event horizon is very large compared to the Planck length $(G\hbar/c^3)^{1/2} \approx 10^{-33}$ cm, the length scale on which quantum fluctuations of the metric are expected to be of order unity. This means that the energy density of particles created by the gravitational field is small compared to the space-time curvature. Even though quantum effects may be small locally, they may still, however, add up to produce a significant effect over the lifetime of the Universe $\approx 10^{17}$ s which is very long compared to the Planck time $\approx 10^{-43}$ s.

The purpose of this letter is to show that this indeed may be the case; it seems that any black hole will create and emit particles such as neutrinos or photons at just the rate that one would expect if the black hole was a body with a temperature of $(\kappa/2\pi)(\hbar/2k) \approx 10^{-6} (M_\odot/M)K$ where κ is the surface gravity of the black hole¹. As a black hole emits this thermal radiation one would expect it to lose mass. This in turn would increase the surface gravity and so increase the rate of emission. The black hole would therefore have a finite life of the order of $10^{71} (M_\odot/M)^{-3}$ s. For a black hole of solar mass this is much longer than the age of the Universe. There might, however, be much smaller black holes which were formed by fluctuations in the early Universe². Any such black hole of mass less than 10^{15} g would have evaporated by now. Near the end of its life the rate of emission would be very high and about 10^{30} erg would be released in the last 0.1 s. This is a fairly small explosion by astronomical standards but it is equivalent to about 1 million 1 Mton hydrogen bombs.

To see how this thermal emission arises, consider (for simplicity) a massless Hermitean scalar field ϕ which obeys the covariant wave equation $\phi_{;ab}g^{ab} = 0$ in an asymptotically flat space time containing a star which collapses to produce a black hole. The Heisenberg operator ϕ can be expressed as

$$\phi = \sum_i \{f_i a_i + \bar{f}_i a_i^+\}$$

where the f_i are a complete orthonormal family of complex valued solutions of the wave equation $f_{i;ab}g^{ab} = 0$ which are asymptotically ingoing and positive frequency—they contain only positive frequencies on past null infinity I^- ^{3,4,5}. The position-independent operators a_i and a_i^+ are interpreted as annihilation and creation operators respectively for incoming scalar particles. Thus the initial vacuum state, the state containing no incoming scalar particles, is defined by $a_i|0\rangle = 0$ for all i . The operator ϕ can also be expressed in terms of solutions which represent outgoing waves and waves crossing the event horizon:

$$\phi = \sum_i \{p_i b_i + \bar{p}_i b_i^+ + q_i c_i + \bar{q}_i c_i^+\}$$

where the p_i are solutions of the wave equation which are zero on the event horizon and are asymptotically outgoing, positive frequency waves (positive frequency on future null infinity I^+) and the q_i are solutions which contain no outgoing component (they are zero on I^+). For the present purposes it is not necessary that the q_i are positive frequency on the horizon even if that could be defined. Because fields of zero rest mass are completely determined by their values on I^- , the p_i and the q_i can be expressed as linear combinations of the f_i and the \bar{f}_i :

$$p_i = \sum_j \{\alpha_{ij} f_j + \beta_{ij} \bar{f}_j\} \quad \text{and so on}$$

The β_{ij} will not be zero because the time dependence of the metric during the collapse will cause a certain amount of mixing of positive and negative frequencies. Equating the two expressions for ϕ , one finds that the b_i , which are the annihilation operators for outgoing scalar particles, can be expressed as a linear combination of the ingoing annihilation and creation operators a_i and a_i^+

$$b_i = \sum_j \{\bar{\alpha}_{ij} a_j - \bar{\beta}_{ij} a_j^+\}$$

Thus when there are no incoming particles the expectation value of the number operator $b_i^+ b_i$ of the i th outgoing state is

$$\langle 0_- | b_i^+ b_i | 0_- \rangle = \sum_j |\beta_{ij}|^2$$

The number of particles created and emitted to infinity in a gravitational collapse can therefore be determined by calculating the coefficients β_{ij} . Consider a simple example in which

the collapse is spherically symmetric. The angular dependence of the solution of the wave equation can then be expressed in terms of the spherical harmonics Y_{lm} and the dependence on retarded or advanced time u, v can be taken to have the form $\omega^{-1/2} \exp(i\omega u)$ (here the continuum normalisation is used). Outgoing solutions $p_{lm\omega}$ will now be expressed as an integral over incoming fields with the same l and m :

$$p_{\omega} = \int \{\alpha_{\omega\omega'} f_{\omega'} + \beta_{\omega\omega'} \bar{f}_{\omega'}\} d\omega'$$

(The lm suffixes have been dropped.) To calculate $\alpha_{\omega\omega'}$ and $\beta_{\omega\omega'}$ consider a wave which has a positive frequency ω on I^+ propagating backwards through spacetime with nothing crossing the event horizon. Part of this wave will be scattered by the curvature of the static Schwarzschild solution outside the black hole and will end up on I^- with the same frequency ω . This will give a $\delta(\omega - \omega')$ behaviour in $\alpha_{\omega\omega'}$. Another part of the wave will propagate backwards into the star, through the origin and out again onto I^- . These waves will have a very large blue shift and will reach I^- with asymptotic form

$$C\omega^{-1/2} \exp\{-i\omega\kappa^{-1} \log(v_0 - v) + i\omega v\} \text{ for } v < v_0$$

and zero for $v \geq v_0$, where v_0 is the last advanced time at which a particle can leave I^+ , pass through the origin and escape to I^+ . Taking Fourier transforms, one finds that for large ω' , $\alpha_{\omega\omega'}$ and $\beta_{\omega\omega'}$ have the form:

$$\begin{aligned} \alpha_{\omega\omega'} &\approx C \exp[i(\omega - \omega')v_0](\omega'/\omega)^{1/2} \\ &\quad \cdot \Gamma(1 - i\omega/\kappa)[-i(\omega - \omega')]^{-1+i\omega/\kappa} \\ \beta_{\omega\omega'} &\approx C \exp[i(\omega + \omega')v_0](\omega'/\omega)^{1/2} \\ &\quad \cdot \Gamma(1 - i\omega/\kappa)[-i(\omega + \omega')]^{-1+i\omega/\kappa} \end{aligned}$$

The total number of outgoing particles created in the frequency range $\omega \rightarrow \omega + d\omega$ is $d\omega \int_{\omega'} |\beta_{\omega\omega'}|^2 d\omega'$. From the above expression it can be seen that this is infinite. By considering outgoing wave packets which are peaked at a frequency ω and at late retarded times one can see that this infinite number of particles corresponds to a steady rate of emission at late retarded times. One can estimate this rate in the following way. The part of the wave from I^+ which enters the star at late retarded times is almost the same as the part that would have crossed the past event horizon of the Schwarzschild solution had it existed. The probability flux in a wave packet peaked at ω is roughly proportional to $\int_{\omega_1}^{\omega_2} \{|\alpha_{\omega\omega'}|^2 - |\beta_{\omega\omega'}|^2\} d\omega'$ where $\omega_2 \gg \omega_1 \gg 0$. In the expressions given above for $\alpha_{\omega\omega'}$ and $\beta_{\omega\omega'}$ there is a logarithmic singularity in the factors $[-i(\omega - \omega')]^{-1+i\omega/\kappa}$ and $[-i(\omega + \omega')]^{-1+i\omega/\kappa}$. Value of the expressions on different sheets differ by factors of $\exp(2\pi n\omega/\kappa)$. To obtain the correct ratio of $\alpha_{\omega\omega'}$ to $\beta_{\omega\omega'}$ one has to continue $[-i(\omega + \omega')]^{-1+i\omega/\kappa}$ in the upper half ω' plane round the singularity and then replace ω' by $-\omega'$. This means that, for large ω' ,

$$|\alpha_{\omega\omega'}| = \exp(\pi\omega/\kappa) |\beta_{\omega\omega'}|$$

From this it follows that the number of particles emitted in this wave packet mode is $(\exp(2\pi\omega/\kappa) - 1)^{-1}$ times the number of particles that would have been absorbed from a similar wave packet incident on the black hole from I^- . But this is just the relation between absorption and emission cross sections that one would expect from a body with a temperature in geometric units of $\kappa/2\pi$. Similar results hold for massless fields of any integer spin. For half integer spin one again gets a similar result except that the emission cross section is $(\exp(2\pi\omega/\kappa) + 1)^{-1}$ times the absorption cross section as one would expect for thermal emission of fermions. These results do not seem to depend on the assumption of exact spherical symmetry which merely simplifies the calculation.

Beckenstein⁶ suggested on thermodynamic grounds that some multiple of κ should be regarded as the temperature of a black hole. He did not, however, suggest that a black hole could emit particles as well as absorb them. For this reason Bardeen, Carter and I considered that the thermodynamical similarity between κ and temperature was only an analogy. The present result seems to indicate, however, that there may be more to it than this. Of course this calculation ignores the back reaction of the particles on the metric; and quantum fluctuations on the metric. These might alter the picture.

Further details of this work will be published elsewhere. The author is very grateful to G. W. Gibbons for discussions and help.

Absorption and emission by interstellar CH at 9 cm

RYDBECK, Ellender and Irvine¹ have recently detected the 9-cm lines of the $^2\Pi_{1/2}$, $J = 1/2$ doublet of interstellar CH. The $F = 1 \rightarrow 1$ transition at 3,335.475 MHz was observed in emission in a wide range of galactic sources ranging from dark clouds to the spiral arms in front of Cassiopea A. The two satellite transitions $F = 0 \rightarrow 1$ (at 3,263.788 MHz) and $F = 1 \rightarrow 0$ (at 3,349.185 MHz) were also observed in emission in several sources.

We have observed the 3,335.475 MHz transition of CH in several southern galactic sources. In RCW38 this line is seen in absorption, while the two satellite lines are seen in emission. In several sources the distribution of CH is found to be extended.

The observations were made on December 10 and 11, 1973, with the Parkes 64-m telescope equipped with a 9-cm parametric amplifier having a noise temperature of 150 K. The telescope beam at 9 cm is 6 arc min. The receiver output was analysed by a 512-channel digital correlator producing a spectral resolution of 19.5 kHz.

The Onsala observations¹ of CH emission at 3,335.475 MHz from Cloud 2 and W12 were confirmed. In Cloud 2 we measured an antenna temperature similar to that found with the Onsala 25-m telescope. For W12 it was 0.23 K, about 50% greater than the Onsala value of 0.15 K; however, at a position 5 arc min south (where the continuum intensity had fallen to one seventh of its peak value) the line signal had decreased by only 30%. A similar situation occurred in RCW36. Thus the CH distribution is considerably more extended than the continuum for these HII regions; in Cloud 2 it must be comparable with the 16 arc min beam of the Onsala 25-m telescope.

In RCW38 the 3,335.475 MHz CH line was observed in absorption (Fig. 1); this is the first case found of absorption by CH. But the two satellite lines at 3,263.788 and 3,349.185 MHz appear in emission, with an antenna temperature of 1.3 K for the former. The pattern of main line absorption and satellite line emission indicates substantial departures from thermodynamic equilibrium in the population distribution.

Fig. 1 9-cm lines of the $^2\Pi_{1/2}$, $J = 1/2$, CH Λ doublet observed in RCW38. Channel spacing is 10 kHz \equiv 2.1 km s $^{-1}$. The local standard of rest radial velocities are based on the rest frequencies determined by Rydbeck *et al.*¹, a, $F = 0 \rightarrow 1$ at 3,263.788 \pm 0.010 MHz; b, $F = 1 \rightarrow 1$ at 3,335.475 \pm 0.010 MHz; c, $F = 1 \rightarrow 0$ at 3,349.185 \pm 0.010 MHz.

A comparison of the CH profiles for RCW38 in Fig. 1 with the 18-cm OH profiles in Fig. 2 (from ref. 2) shows that the CH and OH profiles must contain at least two velocity components. The higher velocity component appears in absorption in OH at 1,665, 1,667 and 1,720 MHz, and in emission in OH at 1,612 MHz, and in CH at 3,264 and 3,349 MHz (and perhaps at 3,335 MHz). The lower velocity component appears in absorption on all four OH lines and in CH at 3,335 MHz, while it is in emission in CH at 3,264 MHz. Detailed comparison of the CH and OH profiles is restricted by the present limited accuracy of the rest frequencies deduced by Rydbeck *et al.*¹ (\pm 10 kHz, equivalent to \pm 1 km s $^{-1}$ in radial velocity).

The CH population distribution in RCW38 required to explain the substantial departures from LTE could be similar to that of the $^2\Pi_{1/2}$, $J = 1/2$ levels of OH in Sagittarius B2 advanced by Gardner and Ribes.³ With their model, maser amplification of the $F = 0 \rightarrow 1$ transition occurs; as it is the region in front of the continuum source which is sampled we would expect the CH emission profile to resemble that for the OH absorption, as it does; we also find that the $F = 0 \rightarrow 1$ line intensity decreases in proportion to the continuum when the beam is pointed 6 arc min north of the source maximum. The model indicates that there is no inversion of the $F = 1 \rightarrow 1$ transition; since we observe an absorption

line the excitation temperature for this transition must be less than the peak brightness temperature in RCW38, which is about 1,500 K (from the emission measure of ref. 4). For the $F = 1 \rightarrow 0$ transition there might not be inversion,

Fig. 2 18-cm lines of the $^2\Pi_{3/2}$, $J = 3/2$ OH Λ doublet observed in RCW38 (from Manchester *et al.*²). Filter bandwidth is 10 kHz \equiv 1.8 km s $^{-1}$. a, 1,612 MHz; b, 1,665 MHz; c, 1,667 MHz; d, 1,720 MHz.

although the excitation temperature is probably higher than for $F = 1 \rightarrow 1$ since the line is observed in emission. Such a population distribution could result from a process of formation or excitation which preferentially filled the upper $F = 0$ level.

Observations of Sgr A at 160 MHz with 1.9 arc min resolution

THE radio source Sgr A, which is located at or near the galactic centre, has now been observed with high resolution (<1 arc min) at several frequencies between 327 and 15 GHz¹⁻⁴. Downes and Martin³ have suggested that two main components are present between 1,400 and 5,000 MHz: Sgr A-West, identified with the galactic nucleus, coincides with the position of the $2.2\ \mu\text{m}$ source of Becklin and Neugebauer⁵. Its size is about 45 arc s and it may contain smaller scale structure^{3,4}. Sgr A-East, about 1.5 arc min to the east, is larger (~ 2.5 arc min) and has a steeper spectrum³ so that it dominates at low frequencies.

Here we extend the high resolution observations of Sgr A down to 160 MHz. This is about the lowest frequency at which observations are possible because the exponential fall-off in flux makes the source undetectable below ~ 120 MHz.

The 160 MHz observations were made with the radio-heliograph at Culgoora, NSW^{6,7}. This instrument has a beam diameter at the zenith of 1.9 arc min (Sgr A passes within 1 arc deg of the zenith). Each observation consisted of a series of about 10 drift scans made with 16 heliograph beams which were arranged to straddle the declination of the source. The 10 drift scans were averaged and used to produce a map of the brightness distribution over an area of 30×17 arc min. Ten such maps, obtained on different occasions and at a variety of hour angles, were superimposed to produce the final map. This procedure minimises the effects due to noise and the presence of other sources in the grating lobes of the radioheliograph. The beam-forming procedure in the heliograph is a switched system in which the area of the sky within about 4 arc deg of the beam is used as a reference. Thus the heliograph does not respond to large scale galactic structure and the temperature of the base level underlying a discrete source is unknown.

Figure 1 shows the brightness distribution of Sgr A obtained by this procedure. There seems to be a small compact source, possibly unresolved, which is apparently superimposed on an extended component about 8 arc min in diameter. The position of the peak, RA 17 h 42 min 33.6 ± 1.0 s, dec. $-28^\circ 58' 40'' \pm 20''$ (1950), is almost exactly the same as that in Little's⁸ map at 408 MHz. This compact source probably corresponds to Sgr A-East.

Krishna *et al.*² have observed Sgr A at 327 MHz using lunar occultations which gave an effective resolution of $\lesssim 1$

Fig. 1 Contour diagram of Sgr A at 160 MHz. The peak main beam brightness temperature, T_p , is 6.3×10^4 K. Contour levels are 10%, 20%, . . . 90% of T_p .

arc min. They claim to have detected Sgr A-West (they refer to it as component "A" but give no flux density) and have suggested that Sgr A-East contains a compact component ("S") which is slightly weaker than Sgr A-West and separated from it by about 1.5 arc min. We have examined each of our individual maps at 160 MHz (as well as the combined map of Fig. 1) and Little's map at 408 MHz (where the resolution is 2.9 arc min) and can find no indication of Sgr A-West or of any splitting into two subsources. If Sgr A-West is no stronger at 160 and 408 MHz than reported by Downes and Martin³ at 1,400, 2,700 and 5,000 MHz (30 f.u.), then we would not expect to see it. We conclude that the presence of Sgr A-West at frequencies lower than 1,400 MHz is not confirmed.

The extended component seen on Fig. 1 probably corresponds to the extended component (designated "E") of Krishna *et al.*², but its shape is considerably different. This component is also prominent on the 408 MHz map of Little⁸, where its shape is generally similar to that on Fig. 1, but the brightness falls off more slowly to the north and the ridge line to the south-east is less prominent than at 160 MHz, probably because of the somewhat lower resolution.

The measured flux density of Sgr A at 160 MHz is 114 ± 16 f.u. (16 f.u. is twice the expected error derived from 10 independent measurements.) This value includes the contributions of both the extended and compact components. On several occasions we have repeated Dulk's⁹ 80 MHz observations of Sgr A. We have made no consistent detections of the source and the upper limit of 5 f.u. remains unchanged.

Figure 2 shows most of the published measurements of the flux density of Sgr A. The measurements of the total flux density between about 400 MHz and 20 GHz can be fitted by a power-law spectrum with spectral index ~ -0.25 . As seen on Fig. 2, however, a more consistent interpretation is obtained if we assume that Sgr A-West has a nearly flat spectrum and the remainder (Sgr A-East) has a straight spectrum with index ~ -0.47 . Sgr A-West, with its small scale structure^{3,4}, could have a more complex spectrum than portrayed on Fig. 2 but no component could have a spectral index very much steeper than -0.5 .

Fig. 2 Spectrum of Sgr A including the present value at 160 MHz. The dashed, dotted and full lines show the assumed spectra for Sgr A-East, Sgr A-West and the total flux density respectively. The falloff at low frequencies was derived from the extrapolated spectrum and the present measurement at 160 MHz. The points marked with crosses and triangles represent observations where Sgr A-East and Sgr A-West were resolved.

We now consider the decrease in flux at frequencies $\lesssim 400$ MHz. Neither a change in the electron energy spectrum nor a mixture of emission and absorption regions within the

source can account for the exponential decrease in flux. Instead it has been attributed to free-free absorption in the interstellar medium between Sgr A and the Earth^{9,10}. If we assume that the intrinsic spectrum of the non-thermal component continues unchanged to low frequencies, then the observed fall-off requires the optical depth at 160 MHz to be $\tau_{160} = 1.34$. The solid curve on Fig. 2 is the theoretical flux density curve which passes through our point at 160 MHz.

We can use the value of optical depth at 160 MHz to estimate the r.m.s. electron density $\langle n_e^2 \rangle^{1/2}$ in the interstellar medium if we make some assumptions about the electron temperature and filling factor. For a hot diffuse medium with $T_e = 5,000$ K distributed over the full 10 kpc to Sgr A we find $\langle n_e^2 \rangle^{1/2} \approx 1.6 \text{ cm}^{-3}$. For cold, dense clouds with $T_e \approx 50$ K occupying 2% of the line of sight we find $\langle n_e^2 \rangle^{1/2} \approx 0.6 \text{ cm}^{-3}$.

Lockman and Gordon¹¹ have observed weak recombination line emission at the position of Sgr A and at other locations within about 0.5 arc deg where no discrete source is visible. The range of T_e and n_e derived from these observations is in generally good agreement with our values above. In interpreting their observations, however, Lockman and Gordon¹¹ and Gordon⁴ have suggested an extremely cold, dense cloud model in which $n_e > 3 \text{ cm}^{-3}$ and $T_e \approx 20$ K. In such an extreme cloud, the absorption observed at 80 and 160 MHz would occur in a distance of only 3 pc. A cloud of this size, if located near the galactic centre, would subtend an angle of only 1 arc min. Our 80 and 160 MHz observations, however, suggest that the absorption is fairly uniform over an area of ≥ 50 (arc min)²; it is not patchy, as would be implied by this cloud model. We conclude that the extremely cold, dense cloud model is unlikely; to cover the source there must be one large cloud or many small clouds, each having a density lower than 3 cm^{-3} , a temperature higher than 20 K or both.

Observations of the radiation from supernova remnants show that absorption in the galactic plane is fairly common¹²⁻¹⁴, although not as strong as for Sgr A, and that the absorption is fairly smooth over the angular extent of the sources¹⁵.

Upper limit to the flux of soft X rays from λ -Sco

DURING a rocket flight on May 26, 1971 which carried a number of large area thin window proportional counters, a soft X-ray source was observed by Bleeker *et al.*¹ in Scorpio. Photons in the energy range 0.37 keV to 1.9 keV were detected from a position error box of approximately 40 square degrees. This admittedly large error box contains the bright star λ -Sco and it was suggested that this object may be the source of the soft X-ray emission that was detected. It is a B1 V star and exhibits a varying radial velocity with a period of about 5.6 d. It has a visual magnitude of 1.62 and its distance is estimated as 100 pc (ref. 2).

Since the identification of an object such as λ -Sco as a soft X-ray emitter would be of considerable importance, we decided to analyse the data obtained with the MSSL low energy (0.5–1.5 keV) X-ray telescope while the Princeton University experiment was observing the same source at ultraviolet wavelengths. The X-ray instrument on Copernicus uses several grazing incidence paraboloidal reflectors with small gas proportional counters located at their foci. A brief description of this instrument has been given elsewhere³; a more complete description is to be published shortly. The 0.5 keV to 1.5 keV telescope system, used to observe λ -Sco, used a 10 arc min. field of view for the observations reported here.

The data were obtained during some 109 h of observation and are presented in Table 1*. They are split into blocks of about 12 h. No data block showed any signal above the background. For the five blocks of data starting on September 19, 1972, the shutter intended to obscure periodically the detector windows was in operation so that the particle background could be estimated accurately. The measured background counting rates were used to produce calculated background rates for the subsequent blocks when the shutter was inoperative.

Although Bleeker *et al.* were unable to estimate the spectral shape of the radiation which they detected, the absence of any signal in their higher energy channel suggests that the spectrum is steep. We have therefore assumed a thermal spectrum, with an electron temperature of 2×10^6 K, in deriving an upper limit to the X-ray luminosity of the source. We emphasise that there is no basis in our data for this assumption but that the results of Bleeker *et al.* show no flux above 1.9 keV. The thermal continuum expression used was of the form:

$$I(E) = K \exp(-E/kT_e) \exp(-N_H \sigma(E)) \quad (1)$$

where K is a normalisation constant, T_e is the electron temperature, N_H the interstellar hydrogen column density to the source² ($\sim 7 \times 10^{19}$ atoms cm^{-2}) and $\sigma(E)$ is the weighted average photoelectric absorption cross section for the material of the interstellar medium⁴. Using equation (1) and the values of the parameters quoted above, a 3σ upper limit was obtained to the source luminosity of $4.0 (\pm 1.0) \times 10^{32}$ erg s^{-1} for the energy range 0.5 to 1.5 keV.

Bleeker *et al.* quoted a value of 2×10^{33} erg s^{-1} so it would seem that the source detected by these workers was not the star λ -Sco. It is possible, as suggested by Bleeker *et al.*, that λ -Sco is a variable. Our observations cover between 50% and 80% of the radial velocity cycle, the uncertainty being due to the lack of an exact period for these variations. If the radial velocity variations were associated with any change in the X-ray flux, it is possible, though in our opinion unlikely, that the present observations might all have coincided with 'off' states of the X-ray emission.

It is possible that λ -Sco emits soft X rays in short bursts.

* See Table 1 on page 90

If this were the case and if the outbursts were of the luminosity suggested by Bleeker *et al.* we would require about 10 min to see a signal of 3σ significance. The data were searched and no significant 10 minute blocks of data were found in 109 h of observation. In addition, a brief survey of this region by Hill *et al.*⁵, carried out about 1 h before the rocket flight of Bleeker *et al.*, failed to detect a significant signal from λ -Sco.

We thank Professor R. L. F. Boyd for support and encouragement, and the many colleagues at Goddard Space Flight Center, the Appleton Laboratory and the Mullard Space Science Laboratory who assisted in controlling the spacecraft and in reducing the data. We have benefited from discussions with Dr J. A. M. Bleeker. K.T.S. acknowledges the support of a Science Research Council studentship.

Upper limit on the low energy interstellar cosmic-ray flux

DETERMINATIONS of the flux of low energy, non-solar cosmic rays extend at present down to 5 to 10 MeV for observations above the Earth¹. But the interstellar flux of cosmic rays below 1 GeV is highly uncertain because of solar modulation effects. The interstellar differential energy spectrum in the range 10 MeV to 1 GeV is usually deduced from theoretical models, by choosing more or less plausible interplanetary diffusion coefficients that will give a fit to the data. The state of sophistication of these theories is, however, still far from satisfactory, since predicted (low energy) values of the demodulated flux can vary by orders of magnitude among different authors, no experimental data on the interstellar flux having been available until now to help in selecting among different models.

In the present communication we wish to point out that there exists now an indirect experimental upper limit on this interstellar low energy flux, based on determinations of the state of ionization of the trace elements in the interstellar gas by the OAO-3 satellite Copernicus². A comparison of these results with those expected if the ionization were due to low-energy cosmic rays allows a direct upper limit to be placed on the number of ionizations per second that an interstellar hydrogen atom would suffer from cosmic rays³. This upper limit on the cosmic ray-induced ionization rate, ζ^{cr} , is

$$\zeta^{\text{cr}} < 4 \times 10^{-17} \text{ s}^{-1} \quad (1)$$

In order to obtain information on the flux from this limit, I use the definition

$$\zeta^{\text{cr}} = 4\pi \delta \int_{T_0}^{\infty} \phi(T) \sigma(T) dT \quad (2)$$

where $\phi(T)$ is the flux (particles $\text{cm}^{-2} \text{ s}^{-1} \text{ sr}^{-1}$ (MeV per nucleon)⁻¹), δ is a factor allowing for secondary electrons and the effect of species with $Z > 1$, T is the cosmic-ray kinetic energy, and $\sigma(T)$ is given by the usual Bethe expression

$$\sigma(T) = 1.23 \times 10^{-20} Z^2 \beta^{-2} \cdot \{6.20 + \log [\beta^2/(1 - \beta^2)] - 0.43\beta^2\} \text{ cm}^2 \quad (3)$$

which is valid down to 0.3 MeV per nucleon.

In the case of cosmic ray protons, δ contains a factor 5/3 to allow for secondary electrons⁴, and a factor 2 to allow for species with $Z > 1$. Some of the expressions proposed for the interstellar proton flux are $\phi^{\text{p}}(T) = 1.2 \times 10^9 (T - 0.75 m_p c^2)^{-2.65}$ particles $\text{cm}^{-2} \text{ s}^{-1} \text{ sr}^{-1}$ (MeV per nucleon)⁻¹ (see ref. 5) or for the proton density, $U(T) = 4\pi c \beta^{-1} \phi(T) = 9.14 \times 10^{-7} [(T + 1.5 m_p c^2)/m_p c^2]^{-2.75}$ particles m^{-3} (MeV per nucleon) (see ref. 6). If one computes with these spectra the ionization rate ζ^{cr} , using equations (2) and (3), it is found that the observational upper limit (1) is not violated, by an ample margin. This remains true even if we integrate below 0.3 MeV per nucleon, using the classical approximation cross section⁷. But the expressions quoted above for the spectrum are known to be inadequate for explaining the kinks and anomalies that appear below a few tens of MeV (refs 8, 9). To account for these, Fisk¹⁰ proposed that, after flattening in the usual manner below 1 GeV, the spectrum steepens again below ~85 MeV, in the form $\phi^{\text{p}}(T) = 4 \times 10^{11} T^{-5.5}$ particles $\text{m}^{-2} \text{ s}^{-1} \text{ sr}^{-1}$ (MeV per nucleon)⁻¹. This flux, in order not to violate expression (1), must cut off sharply at 30 MeV, or if the spectrum turns over with a slope $\propto [\sigma(T)]^{-1}$, then, the peak should be at $T > 30$ MeV. This is more stringent than the limit that would be obtained from the usual energy density arguments by a factor 2. Earlier, and also to explain the low energy kinks, Gloeckler and Jokipii¹¹ had proposed that the spectrum began rising again, below 40 MeV, as $\phi^{\text{p}}(T) = 6.2 \times 10^8 T^{-4.2}$ particles $\text{m}^{-2} \text{ s}^{-1} \text{ sr}^{-1}$ (MeV per nucleon)⁻¹. The observational upper limit here imposes a cutoff at energies $T \geq 20$ MeV. Finally, if one tried to extrapolate the high-energy flux as $\phi^{\text{p}}(T) T^{-2.65}$ down to MeV energies, and interpreted T as kinetic energy throughout (which may not be justified), the cutoff would have to come at $T \geq 50$ MeV. If one considers an arbitrary power law spectrum $\phi^{\text{p}}(T) = \phi_0 T^{-\alpha}$, taking $\sigma(T) \simeq \sigma_0 T^{-1}$ and assuming a cutoff at 1 MeV, one obtains the limit $\phi^{\text{p}}(1 \text{ MeV per nucleon}) < 5 \times 10^2$ particles $\text{m}^{-2} \text{ s}^{-1} \text{ sr}^{-1}$ (MeV per nucleon)⁻¹.

In the case of cosmic-ray electrons, I adopt 1/3 for the positron fraction of the total electron-positron flux, and try to interpret (1) as giving information on the electron flux. In this case $\delta = (5/3)(3/2) = 2.5$ (that is, I neglect proton, and $Z > 1$, contributions to ζ ; if this were not valid, the cutoffs derived below should be lower limits). Cummings *et al.*¹² find a good fit to the observed electron data above 10 MeV, using the diffusion-convection approximation and an assumed interstellar spectrum $\phi^{\text{e}}(T) = 3.16 \times 10^6 T^{-2.5}$ electrons $\text{m}^{-2} \text{ s}^{-1} \text{ sr}^{-1} \text{ MeV}^{-1}$, which is a straight extrapolation of the flux observed above a few GeV. Condition (1) requires this flux to cutoff at $T \geq 6$ MeV, so the lower end of this assumed interstellar spectrum is dubious. In a different investigation, Cummings *et al.*¹³, from an analysis of the galactic non-thermal radio emission, derive a somewhat flatter 'nominal' spectrum $\phi^{\text{e}}(T) = 1.8 \times 10^4 T^{-1.75}$ electrons $\text{m}^{-2} \text{ s}^{-1} \text{ sr}^{-1} \text{ MeV}^{-1}$ down to 80 MeV, and a possible 'high' spectrum, which below 80 MeV could be extrapolated (on the basis of their graphs) as $\phi^{\text{e}}(T) = 5 \times 10^6 T^{-1.75}$ electrons $\text{m}^{-2} \text{ s}^{-1} \text{ sr}^{-1} \text{ MeV}^{-1}$. Proceeding as before, we find that these spectra cannot be extrapolated below 0.1 MeV for the 'nominal' spectrum and below 10 MeV for the 'high' spectrum. For an arbitrary power law spectrum $\phi^{\text{e}}(T) = \phi_0 T^{-\alpha}$, taking $\sigma(T) \simeq \text{con-}$

stant $= 9.3 \times 10^{-20} \text{ cm}^{-2}$ above 1 MeV (this is the transition region for the electron cross section), one obtains, assuming a cutoff at 1 MeV, an upper limit $\phi^*(1 \text{ MeV per electron}) < 1.4 \times 10^5 (\alpha - 1) \text{ electrons m}^{-2} \text{ s}^{-1} \text{ sr}^{-1} (\text{MeV per electron})^{-1}$. The upper limit (1) thus leads to definite restrictions on the flux of low energy cosmic rays. It had been shown¹⁴ that, in order not to produce too much ^{11}B from spallation reactions, a limit could be set on the ionisation rate from protons in the range 5 to 30 MeV, $\xi_{5-30} \lesssim 6 \times 10^{-17} \text{ s}^{-1}$. This restricted the range of low energy cosmic rays that had been postulated for heating the interstellar gas to the range $T < 5 \text{ MeV}$ (see ref. 15). Since my limit (1) of $\xi < 4 \times 10^{-17} \text{ s}^{-1}$ is not restricted to an energy range, it effectively rules out cosmic rays with $T < 5 \text{ MeV}$ also. In fact, the cutoffs, when predicted, happened above this value.

I note that the limit (1) is, strictly speaking, valid within 100 pc from the Sun^{2,3}. In order to use this limit, or the cutoffs derived above, to derive conclusions about the diffuse radio, X-ray or γ -ray background, it should be kept in mind that integrations over a much longer path length are required, and a straightforward use of expression (1) may not be justified for these purposes. As far as solar modulation theories are concerned, the cutoffs derived above are probably more important in the electron case than in the proton case. This is because in the latter case the observed flux at 10 to 20 MeV is representative of a higher energy region in the interstellar spectrum⁵. But the necessity of cut-offs has been demonstrated only for the usual power law types of interstellar spectra discussed above. It may be that other types of spectra can be found to give agreement with the observed spectrum without violating condition (1). If these cutoffs are real, they may provide some information on the sources of cosmic rays. For instance, under the assumption of an isotropic, steady-state injection (such as pulsars and white dwarfs), if we assume that the low-energy particles stream with the Alfvén velocity of the ionized component of the interstellar gas, then since the lifetime of a 20 MeV portion is $\tau \simeq 1.5 \times 10^6 \text{ yr}$, the distance between sources must be $\geq 30 \text{ pc}$. Or, if low energy cosmic rays are injected by supernova events, some information on the frequency or spacing of these events may also be gained from the fact that the surviving cosmic rays must have $\tau \simeq 1.5 \times 10^6 \text{ yr}$. Alternatively, the necessity of a cutoff may not reflect some characteristic of the spatial and temporal distribution of the sources, but rather may be inherent to the acceleration mechanism itself.

I thank M. J. Rees and J. P. Ostriker for comments.

Magnetisation of comets

THE presence of magnetic fields in the plasma tails of comets is suggested by the rayed structures and helical features observed in them¹. According to the present picture of the solar wind-comet interaction (see, for example, ref. 2) it is, however, not at all clear how the interplanetary magnetic field could mix with the cometary plasma in the tail because the solar wind and the associated interplanetary field is separated from the cometary plasma by a contact surface.

Although it has been suggested that the contact surface may be liable to various instabilities such that the interplanetary magnetic field may penetrate it and establish contact with the plasma in the tail³ the viability of the process has not yet been demonstrated by any detailed analysis. It seems therefore legitimate to question if significant magnetic fields can be generated within the coma and sustained there for sufficiently long periods of time.

There are good reasons to believe that the magnetic fields of celestial bodies derive from the hydromagnetic conversion of kinetic energy into magnetic energy in their cores, although the details of the conversion mechanism are less clear. One such mechanism is provided by the well known 'magneto-hydrodynamic dynamo' (see, for example, ref. 4). An alternative and less speculative mechanism is the 'poloidal field amplification' mechanism which is founded on phenomena observed in laboratory experiments⁵ and which has been recently used for a theory of the Earth's magnetic field (H. A. and L. Lindberg, paper presented at the Geophysical and Geochemical Conference in Houston, Texas; January, 1973). Independent of which mechanism is preferred, however, the general requirements for a fluid body to be magnetised are that its volume and electrical conductivity are large enough, that there is sufficient internal kinetic energy to be converted to magnetic energy, and that there is a degree of ordering of the internal (turbulent) velocity field such as would be provided by rotation. The magnetic field H generated should be of the order

$$H = (4\pi\rho v^2)^{1/2} \quad (1)$$

where ρ is the density and v is the velocity of relative motion ('turbulent' velocity).

Clearly gas streaming out radially from a central nucleus cannot produce such magnetic field amplification, but if the nuclear region ($r \lesssim 10^4 \text{ km}$) consists of a supplementary distributed source for the coma gases as has been suggested recently by several authors^{6,7} a turbulent flow with maximum velocities of the order of thermal velocity ($\approx 1 \text{ km s}^{-1}$; ref. 7) may be expected in this region, with the necessary ordering in the turbulent velocity field provided by the rotation of the nuclear region. Taking $\langle\rho\rangle \approx 5 \times 10^{-16} \text{ g cm}^{-3}$ as a typical value in $r \lesssim 10^4 \text{ km}$ (ref. 7) and putting $v = 1 \text{ km s}^{-1}$, we obtain from equation (1) $H \approx 0.01\text{T}$, which is a significant field. Even if the turbulent velocity, v , were an order of magnitude smaller, H would still amount to about 100γ .

It is necessary to check if this magnetic field can be retained for a sufficiently long time. The time of decay τ , of the magnetic field is given by

$$\tau = 4\pi L^2 \sigma \quad (2)$$

where σ is the electrical conductivity (e.m.u.) and L is the scale length of the turbulent eddies.

In estimating the electrical conductivity of a partially ionised gas, as is the one under consideration, it is important to check if the lifetime of the electrons is sufficiently long, for otherwise the conductivity will be provided mainly by the much less mobile positive and negative ions (when it will be decreased essentially by a factor $\sim (m_i/m_e)^{1/2} \sim 100$). Although comets contain highly electronegative gases like OH the lifetime against electron attachment at the relevant densities ($n \approx 5 \times 10^7 \text{ cm}^{-3}$) is more than 10^7 s (ref. 8), about two or three orders of magnitude larger than the ionisation time scales of some of the dominant coma species (for example, CO)⁹. Consequently the appropriate conductivity is the electron conductivity, which is given by¹⁰

$$\sigma = \frac{4 \times 10^{-10} (n_e/n)}{T^{1/2} \langle Q \rangle} \text{ e.m.u.} \quad (3)$$

where $\langle Q \rangle$ is the effective collision cross section for electrons and neutral atoms and T is the electron temperature. Without a better knowledge of both the chemical composition and the photoionization processes in the inner coma it is not possible to estimate n_e/n in $r \lesssim 10^4 \text{ km}$ with any degree of certainty. If, however, we make the not unreasonable assumptions that $n_{\text{co}}/n \approx 0.1$ and that the degree of ionisation of CO in $r \lesssim 10^4 \text{ km} \approx 0.5$, then taking $T \approx 1,000 \text{ K}$ and $\langle Q \rangle \approx 10^{-15} \text{ cm}^2$, we get $\sigma \approx 5 \times 10^{-7} \text{ e.m.u.}$ Once again there is an uncertainty about the value to be ascribed to L , but if we take $L \approx 10^3 \text{ km}$ $\tau \approx 2,000 \text{ yr}$ and if we take $L \approx 10^2 \text{ km}$ $\tau \approx 20 \text{ yr}$. Even if our smallest estimate of τ is too large by two orders of magnitude we still obtain $\tau = 0.2 \text{ yr}$, which is yet of the order of the periods of coma and tail activity of a typical comet.

It therefore seems to us that a comet, when sufficiently close to the Sun, may be able to generate an appreciable internal magnetic field and that the magnetic fields observed in the tail may then result from processes analogous to those producing the Earth's magnetotail.

We thank Professor W. I. Axford for a useful discussion. This work was supported by the Planetology Program Office, Office of Space Sciences, National Aeronautics and Space Administration.

Geochemical evidence for an east-dipping Appalachian subduction zone in Newfoundland

THE concept of plate tectonics explains the present behaviour of the Earth better than any rival hypothesis. Modern plate motion can be observed and measured, but unfortunately much of the evidence is ephemeral. Spreading ridges, trenches, oceanic magnetic lineaments, zones of seismic activity dipping under orogenic belts, and areas of anomalous heat flow are all destroyed or decay as the plate regime evolves. Applicability of the plate tectonic concept to the ancient past must therefore be determined by more indirect geological observations which are often open to more than one interpretation. For example, it can be inferred that melanges should develop in trenches associated with subduction¹, but not all melanges originate in this way and there is presently no easy way of typefying melanges. Thus, if the great variety of presently observed plate interactions existed in the past, geologic data may not be subtle enough to distinguish them and the record may be blurred beyond reasonable interpretation.

Given the limitations of geological data, it seems most reasonable to use the gross regional information rather than the details of local areas as a first basis for evaluating ancient plate tectonics. It also seems more reasonable to accept, at least temporarily, the simplest model suggested by these regional data rather than construct complex models to explain variations in local details.

There are several gross geochemical trends observed across presently active subduction zones. The potassium content of igneous rocks varies systematically across both island arcs²⁻⁴ and Cordilleran mountain chains⁵⁻⁷: with increasing distance from the trench, the potassium content of igneous rocks increases. There is also a systematic zonation of mineral deposits across several active orogenic zones with progressively more lithophile elements being concentrated away from the trench above the subduction zones⁸⁻¹⁰. Although these geochemical trends have not been clearly observed across all presently active subduction zones, there are no substantiated cases where a reverse zonation has been established.

Other geological features which may be systematically related to subduction zones include paired metamorphic belts¹¹, ophiolite emplacement¹², melange zones³, and piles of calc-alkaline volcanic rocks. But these features by themselves are not yet unambiguous indicators of the reality or nature of plate movements in the Paleozoic, and are especially difficult to interpret for directions of dip of paleo-subduction zones.

The various plate tectonic models that have been proposed for the Appalachian-Caledonian mountain system are summarized in Fig. 1. Most of the models presuppose plate tectonics and support the assumption with local geological data of varying reliability and significance. It is noteworthy that all the models based on empirical geochemical data are consistent, and all indicate an ancient subduction zone dipping away from the proto-North American continent in a present easterly or southeasterly direction. The models for Great Britain and Norway (ref. 15 and G. H. Gale and F. M. Vokes, unpublished) are based on the chemical composition of igneous rocks and/or the general zonation of mineral deposits. These geochemical patterns strongly resemble those across presently active subduction zones, and they represent the most direct non-paleomagnetic evidence for Palaeozoic plate movements.

Our data suggesting an easterly dipping Appalachian subduction zone in Newfoundland are derived from a study of both the geochemistry of igneous rocks and the present distribution of mineral deposits. They are supported by

other geological data.

More than 1,200 samples of granitic rocks from thirty-three plutons in Newfoundland have recently analysed in detail¹⁶. These analyses show that, irrespective of geological

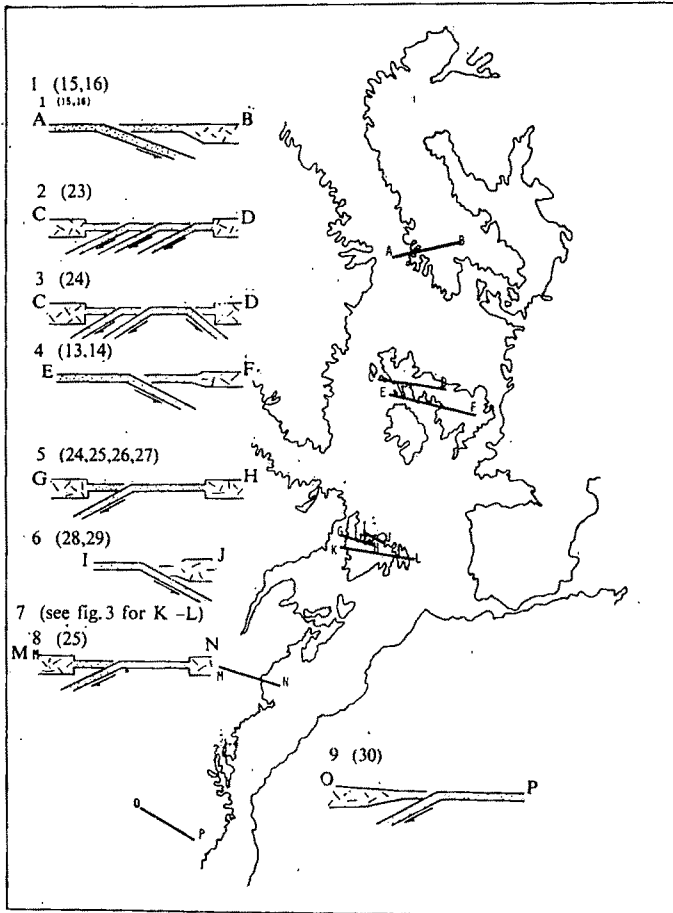

FIG. 1 Summary of plate tectonic models suggested for different sections of the Appalachians-Caledonides. Numbers in brackets next to each model refer to references. Stippled areas represent oceanic-island arc crust and lined areas represent continental crust. Map drawn from reconstruction by Bullard, *et al.*³⁰. Note that only models 1, 4 and 6 are supported by chemical data. *Unpublished results of G. H. Gale and F. M. Vokes.

age, there is a definite eastwards increase in the average potassium content of the plutons in the Central and Gander zones of eastern Newfoundland (Fig. 2). The plutons of the eastern Avalon zone do not seem to follow this trend and are therefore anomalous. This distribution of potassium is similar to that described from western North American and explained by derivation of magma from an east-dipping subduction zone⁵⁻⁷. The Avalon anomaly is comparable with the disjunct observed by Lipman, *et al.*⁷ and interpreted by them as indicating a second subduction zone. Further data may substantiate such an interpretation in Newfoundland, but our present data allow us only to make a very tentative postulation of a second subduction zone responsible for the Avalon plutonic rocks. Preliminary inspection of our data suggests that the main subduction zone dipped at a rather steep angle, perhaps as much as 60°, eastwards. A steep dip would also explain the relative narrowness of the Appalachians as compared to the Cordillera.

The zonation of Newfoundland mineral deposits¹⁷ also indicates an eastward dipping subduction zone (Fig. 3). The observed distribution is like that described by Sillitoe^{8,9} in western North and South America, Mitchell and Garson¹⁰ for the southwest Pacific and G. H. Gale and F. M. Vokes (unpublished) for Norway. Several other features of New-

foundland geology are also satisfactorily explained by a long lived east-dipping subduction zone.

The ophiolites of west Newfoundland and the Burlington Peninsula represent obducted oceanic lithosphere^{25,27}. Their westward emplacement is most simply explained by an over-

FIG. 2 Simplified geological map of the island of Newfoundland. G, Granites; u, ophiolite sequences; C, Carboniferous sediments; SD, Silurian and Devonian subaerial sandstones, conglomerates and shales; V, Ordovician pillow lavas and deep set sediments; CO, Cambrian and Ordovician sandstones, limestones and shales; M, Pre-Ordovician schists and gneisses; PC, Precambrian sediments and lavas; B, Grenville basement gneisses, granites and anorthosites.

thrusting of oceanic lithosphere onto the proto-North American continent above an east-dipping subduction zone, accompanied by an imbricate stacking up of the continental margin sediments under the ophiolites, all of which now form the west coast allochthons.

TABLE 1 Points of geological comparison between eastern and western Newfoundland

Western	Eastern
(1) Grenville Basement.	None definitely known, except possibly in the Gander Lake zone.
(2) Hadrynian plateau basalt volcanism.	Hadrynian acid ignimbrite volcanism.
(3) Fleur-de-Lys metamorphic zone.	Gander Lake metamorphic zone.
(4) Cambro-Ordovician shelf limestones.	Cambro-Ordovician Mn-Fe oxides.
(5) Ophiolites obducted onto western platform.	Ophiolites not obducted, just deformed and intrusive ultramafics.
(6) No post-Grenville granitoid rocks present.	Granitoid rocks possibly ranging from Hadrynian to Devonian in age.

The calc-alkaline piles of early and middle Ordovician volcanic rock with associated sediment in Notre Dame Bay would represent the volcanic island arcs associated with such eastward subduction.

The Gander Lake metamorphic belt would result from metamorphism along a continental margin above the subduction zone. This zone passes eastwards into the Avalon Platform continental crust, which was then a Basin and

Range type regime marked by strong faulting and bimodal basalt-ignimbrite eruptions. This Cordilleran type mountain chain might have been the long lived New Brunswick geanticline of Schuchert¹⁸. Its existence might also explain the inferred long age span of granites of the Gander Lake zone¹⁹.

The western Fleur-de-Lys metamorphic and plutonic zone would be explained according to the model of an east-dipping subduction zone as being the result of the overriding effect of oceanic lithosphere, that is subduction under oceanic lithosphere, with a resulting sinking, deformation and melting at the base of the continental crust.

FIG. 3 Summary of geochemical and metallogenic evidence supporting an eastward-dipping Appalachian subduction zone in Newfoundland, as compared to analogous areas elsewhere. A, Variation in K across the Central Sierra Nevada Batholith (after Bateman and Dodge⁵). B, Metal zoning of western North and South America (after Sillitoe⁸). C, Metal zoning across Circum-Pacific island arcs (after Mitchell and Garson¹⁰). D, Variations in K across eastern Newfoundland. The K data points are means for individual plutons (>1,200 analyses in total), the positions of which are plotted as distance of pluton centers from the western margin of the Gander Lake metamorphic belt, which is taken as the eastern Appalachian continental margin. E, Metal zoning in eastern Newfoundland. F, Schematic plate tectonic interpretation of the data described above.

Although the gross geological symmetry of Newfoundland²⁰ can be explained by the bringing together of two

continental margins²¹ we emphasise that there is a fundamental asymmetry evident on a finer scale (Table 1, Fig. 2). It can be explained as the result of an east-dipping subduction zone. The most striking aspect of this asymmetry is that there are no post-Grenville granitoid rocks on the western platform, that is, they seem to terminate abruptly at a line approximately along the Cabot fault. This line is taken as the westward limit of subduction.

The inferred existence of a subduction zone active for more than 250 m.y. suggests that the proto-Atlantic was a rather large ocean basin.

The chemical analyses of granitoid rocks on which this paper is based were obtained during a study for the Newfoundland Department of Mines and Energy under their DREE program and they are published with the permission of the Department. It was also supported by the National Research Council of Canada.

New approach to surface seawater palaeotemperatures using $^{18}\text{O}/^{16}\text{O}$ ratios in silica of diatom frustules

THE oxygen isotopic composition of calcium carbonate and silica deposited by organisms in water depends on the temperature and the isotopic composition of the water¹.

As deep seawater temperatures probably did not vary during the Pleistocene, the variations of the oxygen isotopic composition of the sea during this period can be followed by analysis of the $^{18}\text{O}/^{16}\text{O}$ ratio in the tests of deep benthic foraminifera². Shallow pelagic foraminifera grew in waters where significant temperature variations seem to have occurred in glacial periods. Yet the $^{18}\text{O}/^{16}\text{O}$ ratio in their carbonate tests does not show such variations. An explanation of this phenomenon lies in the ability of pelagic foraminifera to adjust the depth at which they live so as to minimise the effect of temperature variations on their biology^{2,3}.

To be able to follow oceanic surface palaeotemperatures by the variations of the $^{18}\text{O}/^{16}\text{O}$ ratio in a compound, it is necessary to be sure that the site of formation was really near the surface. Diatoms, most of which form skeletons of silica, grow in the upper 40 m because they require light for photosynthesis. Consequently, the $^{18}\text{O}/^{16}\text{O}$ ratio of their skeletons is dependent on the $\text{H}_2\text{ }^{18}\text{O}/\text{H}_2\text{ }^{16}\text{O}$ ratio and on the temperature of the surface water. Since the $\text{H}_2\text{ }^{18}\text{O}/\text{H}_2\text{ }^{16}\text{O}$ variations within a water column are very small, the $^{18}\text{O}/^{16}\text{O}$ ratio of benthic foraminifera of the same area can be used as an index of $\text{H}_2\text{ }^{18}\text{O}/\text{H}_2\text{ }^{16}\text{O}$ variations. Then, by comparing the variation of the $^{18}\text{O}/^{16}\text{O}$ ratio in silica from diatoms from different horizons of a core with that of benthic foraminiferal carbonates of the same horizons, it should be possible to calculate the surface water variations of $^{18}\text{O}/^{16}\text{O}$ ratios and temperatures during the past.

To test whether biogenous silica can be used for this purpose, it was necessary to check that it is formed in isotopic equilibrium with water, and to find the temperature relationship for $^{18}\text{O}/^{16}\text{O}$ fractionation between silica and water. For this study I analysed recent or living specimens, formed under known conditions of temperature and isotopic composition of the water.

Oxygen extraction from silica was carried out using BrF_3 by a method modified⁴ from that described by Clayton and Mayeda⁵. Detrital minerals, organic matter and the hydration water of the biogenous silica were separated from the specimens analysed. Removal of all of the detrital minerals

requires many filtrations and ultrasonic washings, and much settling and decanting⁴. Slow solution of carbonates with 0.1 M HCl is possible without oxygen isotopic exchange between the silica and the water. Organic matter is more difficult to destroy without interfering with the oxygen of the silica. But, since the organic oxygen has an isotopic composition approximately 15‰ lower, and is present as the major part of the total oxygen in recent samples, such a separation is necessary. We attribute the variations of oxygen isotopic composition seen by Mopper and Garlick⁶ on unwashed radiolaria to the slow degradation of the organic matter⁴. It is possible, using slow oxidation by NaOCl, to destroy more than 99% of the organic matter, even in fresh specimens⁷. A more serious contamination problem results from the physical nature of biogenous silica. This silica is formed in a low crystalline, highly hydrated state. In a few million years, the crystallinity increases, with progressive loss of water. This process can be accelerated by heat: The water trapped in the pores of the structure, which is in isotopic equilibrium with the environment, is volatilized by heating above 100° C in vacuum, but without apparent exchange with the oxygen of the silica. The remainder of the water (approximately 2 to 4% by weight of the silica) is partly chemically bound, in the hydroxyl form, to the silicon atoms. Heating at about 1,000° C in vacuum removes this water⁸ by increasing the crystallinity towards tridymite, cristoballite, or even quartz. To see the effect of this dehydration procedure on the isotopic composition of biogenous silica, the $^{18}\text{O}/^{16}\text{O}$ ratio of a Miocene diatomaceous earth from Cantal (France) was determined, after heating in vacuum for 1 h different samples of the same weight at different temperatures (Fig. 1). The isotopic composition is changed in a non-reproducible manner by heating between 500° C and 600° C. As most of the water is ejected in the first few minutes of heating, 1 h of treatment permits a reproducible dehydration. To ensure that the water is volatilised at constant temperature, we use a modified furnace, in which the sample reaches the plateau temperature in a few seconds. The scatter of the low temperature data indicates that rapid but incomplete isotope exchange occurs during dehydration under these conditions, partly because of interactions with residual organic matter lost at these temperatures⁹. On the other hand, the isotopic composition of specimens dehydrated at temperatures greater than 800° C is nearly constant and about 1‰ higher than that of specimens heated at temperatures below 500° C. There is only weak isotopic fractionation during exchange be-

tween water and silica at these temperatures. So, if exchange occurs between silica and water during the dehydration process, the isotopic composition of the sample would remain constant. As the corresponding weight loss is only about 3%, the 1‰ ^{18}O enrichment is consistent with a water loss of isotopic composition approximately -40‰ compared to the silica. To these freshwater diatomites, $\delta^{18}\text{O} \sim 32\text{‰}$ relative to Standard Mean Ocean Water (SMOW), would correspond a water of isotopic composition -8‰ relative to SMOW, a value consistent with present freshwater composition in the sampling area. The 1‰ change in isotopic composition then can be interpreted as corresponding to a dehydration sufficiently fast to preclude isotopic exchange between water and silica. Then the isotopic composition of the silica dried above 800° C represents that of the silica as formed originally. This method has the advantage of producing crystalline, marginally hygroscopic, stable silica. The dispersion of measurements of fossil specimen isotopic composition was found to be less than $\pm 0.1\text{‰}$.

In order that silica formed under various regimens of water temperature and isotopic composition might be studied, newly deposited diatom frustules and siliceous spicules from living sponges were analysed. Preliminary results of the measurements are reported in Table 1, including the temperature and the $\delta^{18}\text{O}$ of the water during skeleton formation (as defined in ref. 9). Temperature during skeleton formation is presented as a function of the fractionation factor in Fig. 2. The regression line, based on the best defined point: $t = 5 \pm 0.3^\circ \text{C}$; $\Delta(\text{SiO}_2\text{-H}_2\text{O}) = 40.0 \pm 0.2\text{‰}$ is described by the equation: $t(^{\circ}\text{C}) = 5 - 4.1 (\delta\text{SiO}_2 - \delta\text{H}_2\text{O} - 40)$. The 1 σ uncertainty of the slope is ± 0.4 .

Fig. 1 Isotopic composition of the diatomite from LaBade (Cantal, France) after dehydration at different temperatures.

For palaeotemperature estimation, this uncertainty should be reduced by further analyses of warmer water specimens. But, within the present precision, the isotopic fractionation between water and either sponge spicule silica or diatom frustule silica is identical. There is then no indication of biogenic fractionation. In addition, data from freshwater samples from Lake Pavin and Lake Myvatn fell perfectly on the regression line, although these specimens were formed in water of $\delta^{18}\text{O}$ considerably different from the SMOW. The non-dependence of the isotopic enrichment of siliceous skeletons on the isotopic composition of the water in which they were formed is considered to indicate formation under conditions of isotopic equilibrium. This hypothesis is strengthened by the results of Clayton, O'Neil and Mayeda¹⁰ on the quartz water fractionation under pressure at temperatures over 200° C. We have shown⁴ that an extrapolation to room temperature of these results is valid, and gives a perfect agreement with our analysis.

To use $^{18}\text{O}/^{16}\text{O}$ in diatom silica for a Pleistocene palaeotemperature record, we must be sure this silica preserves its original isotopic composition on a scale of millions of years.

Some analyses of Miocene diatoms from fresh or marine waters exposed for a few million years to ground waters indicate no exchange in that period of time with the local ground waters⁴. But the long term variations, as observed by Degens and Epstein¹¹, restrict the application of this method to samples younger than some 10^7 yr.

Fig. 2 Isotopic fractionation between water and silica from either diatoms or sponges, as a function of the temperature of formation. Centre line is regression line; outer lines define 1 σ envelope. \circ , Diatoms (frustules); \bullet , sponges (spicules).

In conclusion, the relationship found for the silica-water isotopic fractionation ($t = 5 - 4.1 (\delta\text{SiO}_2 - \delta\text{H}_2\text{O} - 40)$) is very similar to the known relationship for carbonates ($t = 16.9 - 4.2 (\delta'\text{CaCO}_3 - \delta'\text{H}_2\text{O})$). The slopes of these regression lines are too close to allow, through comparison of their $^{18}\text{O}/^{16}\text{O}$ ratios, the calculation of the temperature of the water in which siliceous and carbonate skeletons were formed simultaneously. But these results indicate that the measurement in sediments of $\delta^{18}\text{O}$ in frustules of diatoms and in associated tests of benthic foraminifera may be used to follow the variations of surface water temperature during the Pleistocene.

Glacial advance relative to volcanic activity since 1500 AD

THERE may be a connection between the periodicity of glacial advance and the occurrence of volcanic eruptions. Lamb¹ has presented a graph which shows a similar curve for Arctic sea ice off Iceland and great Icelandic volcanic eruptions since 870 AD and Bray² found the number of maximum advances of alpine glaciers since 1680 AD is significantly related ($\chi^2 = 7.8$, $P < 0.01$) to intervals with a volcanic dust veil index of 1,000 or greater. The volcanic dust estimates have now been extended to 1500 AD (ref. 1) and in this paper I analyse the relationship between these estimates and records of maximum glacial advance from 1500 AD to the present.

Glacial activity was assessed by a compilation of maximum advance dates, defined as all advances which reached the terminal moraine or its near vicinity. Only dates based on historical observations or on distortions in the growth rings of trees standing at the time of glacial advances were selected, in order to ensure a maximum accuracy. A total of 128 dates were compiled from summary studies of which 16 dates were from North American trees²⁻⁵ and 112 were from European historical observations^{2,6-8}. The North American and European dates were synchronous.

The compiled maximum glacial advance dates are shown in Table 1 at 20 yr intervals together with Lamb's estimate of the amount of volcanic dust in the atmosphere of the Northern Hemisphere (from Table 7a of ref. 1). Both the glacial advance and volcanic dust data have a series of similar peaks during the 17th, 18th and 19th centuries, with lower values in the 16th and 20th centuries. There is a significant positive correlation ($r = +0.43$, $P < 0.05$) between the glacial and volcanic activity data in Table 1 which supports the results of the previous study². The basic data summarised in Table 1 show a tendency for glacial advance to follow major volcanic eruptions which may reflect the lag between the time of ice buildup and its maximum advance (as noted below).

A mechanism for the apparent relationship between glacial advance and volcanic eruption has been suggested²: After a major volcanic eruption, there is a global temperature decline from atmospheric dust for up to 3 or 4 yr or more². During this decline, there are colder springs and summers¹ and as a result, some precipitation which usually falls as warm storms over the icefields (thus promoting ablation), falls instead as snow. These snowfalls can increase the summer albedo of the icefield up to four times (albedo old ice ~ 20%, new snow ~ 80%) and together with a decrease in the number of warm storms is a major influence² in producing a strong positive ice balance and a consequent glacial advance.

This proposed sequence of major volcanic eruptions followed by several years of cold summers and then by glacial advance is supported by historic and phenologic data. Of

TABLE 1 Maximum glacial advances and atmospheric volcanic dust in the Northern Hemisphere 1500 to 1960 AD

the 102 late wine harvests which occurred on or after October 10 from 1500 AD to 1880 AD in France (data converted to a national basis from Appendix 12 of ref. 6), 25 occurred in the 59 yr with volcanic eruptions with DVI (Dust Veil Index) of 300 or greater ($\chi^2 = 6.3$, $P < .01$). A significant relationship ($\chi^2 = 27.0$, $P < 0.001$) with volcanic eruption was also determined for the 128 maximum glacial advance dates of which 111 occurred within 24 yr after the 23 volcanic eruptions with a DVI of 1,000 or greater from 1500 to 1970 (Table 2). The distribution of the lag between volcanic eruption and glacial advance shown in Table 2 is in agreement with studies³ of the interval between ice buildup in the icefield and subsequent maximum glacial advance.

Sequences of volcanic eruptions followed by cold summers and then glacial advance are shown in Table 3 which summarises: (1) all the intervals of 10 yr or less with volcanic eruptions with a total DVI of at least 1,000 (from Appendix I, ref. 1); (2) all years of cold summers in England (ref. 1, page 494) and France (ref. 6, pages 56, 58, 60) and years of famine and food shortage due to cold summers in western Europe and Japan (ref. 2, Table VII; ref. 1, page 494; ref. 6, pages 66-68, 92); and (3) the 128 glacial advance dates. The most notable sequences in Table 3 are those following the two largest volcanic eruptions, 1815 and 1835. The 1815 eruption was the peak of a series of eruptions from 1811 to 1817. Cold springs and summers, late wine harvests and food shortages occurred from 1812 to 1817 and included the "year without a summer" in 1816. A major glacial expansion began in 1814, maximum advances were reached from 1817 to 1824 and ice retreat began in 1819.

Years which had eruptions > 1,000 DVI; †DVI could be as high as 3,000 to 3,500; ‡DVI estimated from temperature anomalies; ¶underlined glacial phases are those emphasized by Ladurie for western Europe (pp 195, 211 ref. 5).

The 1835 volcanic eruption, together with subsequent eruptions in 1845 and 1846, was followed by cold springs and summers, late wine harvests and food shortages in 1833–39 and the 1840s with a major glacial advance period occurring from 1840 to 1855. All the glacial expansion phases with five or more advances were preceded by major volcanic eruptions except that of 1736–43 which was preceded by a period of cold summers, food shortages and severe famine in 1740–42, but by only a minor volcanic eruption of 700 DVI from 1730–36. The 1527–29 food shortage period was apparently not related to a preceding volcanic eruption.

The role of global temperature (perhaps controlled, in part, by solar activity²) in the proposed volcanic eruption-glacial advance sequence may be to determine the number and magnitude of glacial advances. This may be shown by the relatively lower number of advances following volcanic eruptions during the generally warmer period¹¹ of the mid to late 18th century compared with the preceding and following centuries which had colder temperatures¹¹ and more numerous glacial advances following volcanic eruption. It may also explain the lower number of ice advances during the warmer temperatures of the 12th and 13th centuries² when there was a volcanic activity peak¹, compared with the large number of ice advances following volcanic eruption during the colder temperatures² of the 17th and 19th centuries.

There is evidence that, since the Pleistocene, periods of intense volcanic activity may have coincided with major ice advance phases. There were three well dated major volcanic activity periods¹ in the Southern Andes: from 50–450 BP, from 2150 to 2450 BP and from 4720 to 5450 BP. The dates for the three main Neoglacial ice advance phases have been

listed⁹ as 50–450 BP, 2600–2800 BP and 4500–5000 BP. Two of these Neoglacial phases almost exactly correspond with the Andean volcanic activity periods and the second Neoglacial phase, which peaked from 2600–2800 BP extended from 2300 to 2900 BP (refs 9, 12–17). A fourth Andean volcanic period has been tentatively dated around 8950 BP and there was an ice advance phase^{17–19} around 9200 to 9300 BP.

Quantitative Spectrochemical Analyses of Feldspars by Ion Bombardment

WHEN the surface of a solid target is bombarded with energetic ions or neutral atoms, spontaneous emission of ultraviolet and visible radiation is observed. When the radiation is analysed by a spectrometer, it is shown to contain characteristic lines of the constituent elements in the solid^{1–4}. It has also been shown that this radiation is caused by the decay of excited atoms ejected from the target surface^{4,5}. The photon emission process is more efficient in insulating targets than metallic targets. This is because of the existence of radiationless de-excitation processes which compete with radioactive decay in the case of metals but not in the case of insulators^{1,6}. The intensities of the spectral lines are directly proportional to the bombarding ion beam current⁷, that is, directly proportional to the number of sputtered particles since the sputtering yield (sputtered atoms per incident ion) for a particular material is invariant if the ion energy is constant providing that the surface conditions do not alter during sputtering. In a previous report¹, one of us suggested that the photon emission phenomenon may provide a new method for chemical analysis of solids, and subsequently White *et al.*³ demonstrated the detection sensitivity, for example 1 part per 10⁶ for sodium in a silicate glass, which could be achieved with this technique. This communication describes some quantitative analyses of a number of feldspars. The analyses were made by comparing the intensities of the emission lines of the major constituents in these materials. In our analyses, we assume that diffusion does not occur to an appreciable extent so that the relative sputtering rates are directly proportional to the atomic concentrations in the target.

Provided that self-absorption is negligible (because the 'vapour' density of absorbing atoms is low), then we have the condition for spectrochemical analyses (intensity is directly proportional to concentration).

The apparatus, which we shall refer to as IBSCA (ion beam spectrochemical analyser⁸), is identical to the one described previously¹ with the exception that in place of the medium quartz spectrograph, the light was analysed in the present work by a grating monochromator with a cooled photomultiplier as detector. The light intensity, being very low, was measured by a standard a.c. chopping technique.

The analysis procedure was carried out as follows. First, the results of the electron microprobe analysis of a particular feldspar 112 was chosen as standard for all the subsequent analyses. Then the ratios of the intensities of Si 2882 : Al 3093, Si 2882 : Al 3944, Si 2882 : Al 3962, Si 2882 : Fe 3737, Ca 3934 : Na 5890, Ca 3968 : Na 5890, Ca 4227 : Na 5890, and K 7665 : Na 5890, were taken. By comparing the intensity ratios of each unknown feldspar with those of 112, we could calculate the concentration ratios. Using the fact that in a unit cell of feldspar there are thirty-two oxygen atoms, sixteen atoms shared by Si, Al and Fe, and four atoms shared by Ca, Na and K, we could work out each individual atomic concentration in terms of thirty-two oxygens. Unfortunately, we could not analyse the oxygen content in the feldspars accurately because of the presence of oxygen impurity both in the argon gas used for producing the ion beam and in the target chamber, possibly due to contamination of water vapour; otherwise the oxygen 7772 line could have been used as a reference line. (This contamination can probably be removed by using a 4A zeolite and more efficient trapping with liquid nitrogen.) We have therefore chosen to carry out our analyses in the manner described rather than comparing intensities of a particular line directly across samples since the present method minimises uncertainties which may arise due to a change in sputtering conditions, for example variations in ion current and chamber pressure. Since the specimen holder in the present apparatus only allows one sample to be analysed at a time, the changing of samples might therefore cause sputtering conditions to vary from one sample to another. The method of analysis adopted, however, assumes only that the sputtering conditions did not vary during an experimental run on a particular sample.

The analyses of seven feldspars are given in Table 1. The electron microprobe analyses by N. Ware (private com-

munication) are also shown for comparison. Electron microscopy has shown that the substructure of these feldspars is on a scale considerably less than 1 μm ^{9,10}. The electron microprobe has a spot size of about 10–100 μm diameter whereas, in IBSCA, the area under investigation was determined by the monochromator slit width which was 150 μm . It is therefore expected that the microprobe and IBSCA should produce similar results. As can be seen from Table 1, the two sets of results are in good agreement. Slight variations in compositions are expected, because different samples (of the same materials) were used for the IBSCA and microprobe analyses. Two chemical analyses¹¹ of feldspar 190 are also shown in Table 1 to demonstrate the degree of uncertainty involved in the determination of the composition of feldspars.

During our investigation, the following conclusions on IBSCA as an analytical instrument have emerged. (1) The apparatus costs considerably less than other comparable analytical instruments because of its simplicity. The estimated cost of constructing such an apparatus is approximately from \$4,000 to \$10,000 depending on the degree of sophistication required. (2) Multi-element analysis is easy to carry out and no elaborate preparation of the sample is required. (3) In the present method, the area of investigation is effectively selected by the variable slit of the monochromator. If the slit can be replaced by a small circular aperture, it will become a microprobe with mechanical scanning facilities. Its ultimate performance as a microprobe is limited by a spatial resolution of ~ 10 μm assuming the photon-emitting sputtered particles leave the target surface with energies ≤ 10 eV¹. (4) The apparatus can detect light elements down to hydrogen. (5) As the method essentially carries out analysis of the surface, it can be used to measure the concentration profile in a solid as successive surface layers are sputtered away. (6) The line spectra contain very few lines compared to ordinary spectrochemical analysis by arc discharge but more than just resonance lines. This makes identification of elements a very rapid and easy process. (7) With suitable refinements, IBSCA can be used as a research instrument due to its probe characteristics. But as it stands, it can be a very useful field or industrial instrument due to its great simplicity.

In view of the possibility of significant applications, a new IBSCA apparatus using a duoplasmatron ion source to deliver a stable and high current density ion beam and a multiple-target specimen chamber to facilitate rapid and direct com-

parison of intensities is under construction for improved performance.

We thank Mr N. Ware of the Australian National University for carrying out the electron microprobe analyses and Mr R. G. Turner for useful suggestions.

BIOLOGICAL SCIENCE

Inhibitor of vesicular stomatitis virus transcriptase in purified virions

VESICULAR stomatitis virus (VSV) particles contain an RNA-dependent RNA polymerase which gives rise *in vitro* to RNA molecules of the same size and polarity as the mRNA found *in vivo*¹⁻³. It is not clear which structural protein(s) represents the enzymatic activity. Only five proteins (L, G, N, MS, and M, with possibly some additional minor constituents) are detected in the virions⁴, and several studies have suggested that neither the G protein (glycoprotein surface spike) nor the M protein (membrane protein), nor even associated membrane lipids are necessary for transcriptase activity⁵⁻⁷.

Active polymerase has been reconstituted from two inactive fractions, one containing the ribonucleoprotein core and the other, the remainder of the detergent-solubilized proteins⁸. In such a case some components of the virion, in addition to the polymerase itself, may modify or control the transcriptase activity. We report here that VSV particles contain a specific inhibitor of the virion polymerase.

The presence of such an inhibitor was suggested by the results presented in Fig. 1. Polymerase activity measured as a function of virus concentration, was strongly inhibited when virus concentrations were high. This was not due to an early shut-off of *in vitro* activity since under these conditions the kinetics of incorporation were similar for both high and low concentrations, slowing down between 3 and 5 h after the start of the reaction. Various modifications of the reaction cocktail established that none of the components were limiting in inhibiting conditions. Both VSV serotypes—Indiana and New Jersey displayed similar concentration-dependent inhibition, which was the same for virus grown in HeLa as well as BHK₂₁ cells. Further purification of the virus on tartrate-density gradients caused some loss of inhibitory activity for New Jersey VSV but not

Fig. 1 Virion polymerase activity as a function of virus concentration. The cells, virus sources, and growth of the virus were as described in detail elsewhere⁸. Monolayers of BHK₂₁ cells were infected at a multiplicity of infection of 10 with the Indiana VSV serotype. The media were collected after 12-16 h at 37°C and clarified by spinning at 5,000g for 20 min. All operations were carried out at 4°C. The supernatants were spun at 19,000 r.p.m. for 3 h in a Spinco type 19 rotor. The virus pellets were resuspended in small volumes of 0.05 M Tris-Cl, pH 7.5, buffer and sonicated briefly to disrupt clumps. The sonicates were layered on 12 ml 15-45% sucrose gradients in TK buffer (10 mM Tris-Cl, pH 7.7, 100 mM KCl) and spun at 32,000 r.p.m. for 35 min in the Spinco SW 41 rotor. The single visible band of standard particles (no defective interfering particle bands under these conditions) was collected with a Pasteur pipette and stored on ice until assayed. The concentration of virus protein was determined using the relationship 1 mg virus protein per ml equals 3 A₂₆₀ units (M. E. Reichmann, personal communication). Transcriptase assays were carried out by mixing equal volumes of virus suspension diluted in 25% sucrose in TK buffer with equal volumes of polymerase cocktail. The final concentration of the components in the total reaction mixture was as follows: 50 mM Tris-Cl, pH 7.7; 100 mM KCl; 5 mM MgCl₂; 0.1% mercaptoethanol; 0.02% Nonidet P-40; 1 mM each of ATP, GTP, and CTP; 0.1 mM cold UTP; 2.5 μCi-ml⁻¹ ³H-UTP; and approximately 10-15% sucrose. ³H-UTP incorporation was measured on 50 μl samples after 2 h of incubation at 28°C by the method of Blatti *et al.*⁹ Under these conditions incorporation of 1 nmol of UMP is equivalent to 14,000 c.p.m.

for Indiana (see below). The phenomenon could also be demonstrated by adding ultraviolet-irradiated virus (inactive in the polymerase reaction) to standard active virus (Table 1) or by adding defective interfering particles which have little or no transcriptase activity¹⁰ (data not shown). Thus, transcription by the inhibiting virus preparation was not a prerequisite for inhibition.

Preliminary experiments with virus purified through sucrose gradients only, suggested that the inhibitor was serotype-specific. Table 1 shows the results of one such experiment in which Indiana and New Jersey ultraviolet-irradiated virus preferentially inhibited their own serotype polymerase. Several experiments, however, showed either partial specificity or none. Some of this variability may have been caused by contaminating nucleases, which are often present in virus preparations purified on sucrose gradients but not in those density-banded on tartrate gradients (L. P. Villareal, personal communication).

When the virus was purified further through tartrate density gradients the results shown in Fig. 2 were obtained

TABLE 1 Homotypic compared with heterotypic inhibition of *in vitro* transcriptase with sucrose-purified VSV

	c.p.m.
Indiana control	5975
Indiana control + ultraviolet-Indiana	1396
Indiana control + ultraviolet-New Jersey	5390
New Jersey control	5442
New Jersey control + ultraviolet-Indiana	5778
New Jersey control + ultraviolet-New Jersey	2433

Indiana and New Jersey VSV were purified as described in Fig. 1. Virus suspensions in TK-buffered sucrose were irradiated in small nitrocellulose cups at a distance of approximately 6 cm from an ultraviolet sterilizing lamp (G8T5-General Electric) for 6 min. Irradiated virus never incorporated more than 1-2% of controls. Transcriptase assays were carried out as in Fig. 1 except for a final ^3H -UTP concentration of $25 \mu\text{Ci ml}^{-1}$. Control viruses were adjusted to $45 \mu\text{g}$ virus protein per ml and ultraviolet-viruses, to $675 \mu\text{g}$ virus protein per ml final concentration. The c.p.m. listed refer to total incorporation per $30 \mu\text{l}$ sample after 4.5 h at 28°C .

repeatedly. Clearly under these conditions, Indiana VSV polymerase was inhibited specifically by homotypic ultraviolet-irradiated virus but not by heterotypic virus, which was somewhat stimulatory (Fig. 2A). New Jersey VSV polymerase, however, showed a different pattern of response when either serotype was added. Both New Jersey and Indiana ultraviolet-irradiated virus caused early inhibition of incorporation followed later by stimulation (Fig. 2B). Thus, tartrate-purified New Jersey virus did not cause sustained inhibition of either serotype polymerase. It is not known why homotypic inhibition is lost for the New Jersey serotype virus on further purification.

The extent of the inhibition and stimulation of New Jersey polymerase in Fig. 2B, as well as the heterotypic stimulation of Indiana polymerase (Fig. 2A), varied in different experiments, but the homotypic Indiana inhibition was always considerable and readily observed. It is not clear whether these various phenomena are reflections of one or more activities in the preparations.

FIG. 2 Serotype specificity of transcriptase inhibition with tartrate-purified virus. Indiana and New Jersey VSV were further purified by layering on 15-45% NaK-tartrate gradients and spun in the Spinco SW 41 rotor at 37,000 r.p.m. for 3 h at 4°C . The virus bands were recovered and dialysed against TK buffer. Transcriptase assays were carried out as in Table 1. Control preparations contained $50 \mu\text{g}$ virus protein per ml and the ultraviolet preparations were added to a final concentration of $800 \mu\text{g ml}^{-1}$. A, Indiana polymerase; B, New Jersey polymerase; \circ , control; \bullet , plus ultraviolet-irradiated New Jersey virus; $-\bullet-$, plus ultraviolet-irradiated Indiana virus.

The effect of graded amounts of ultraviolet-irradiated virus was examined in experiments carried out in parallel to those of Fig. 2. The totals after 7 h of incorporation were used to construct the curves shown in Fig. 3. In agreement with the previous results, Indiana showed strong homotypic inhibition, while New Jersey polymerase was not inhibited by either serotype. The inhibition reached a maximum of approximately 80% at a particle ratio of approximately 5 ultraviolet-irradiated virus:1 active virus. On the other hand, stimulation of polymerase activity did not reach a maximum with increasing amounts of irradiated virus.

We conclude that the inhibitory activity has some type specificity. It is therefore likely that this phenomenon is

FIG. 3 Polymerase activity versus ultraviolet-virus concentration. The activities plotted are explained in the text and in the legend for Fig. 2. \circ , plus ultraviolet-irradiated New Jersey virus; \bullet , plus ultraviolet-irradiated Indiana virus.

FIG. 4 Loss of inhibitor activity at 37°C in the presence of Nonidet P-40 detergent. Indiana VSV purified through sucrose and tartrate gradients was ultraviolet-irradiated as before and incubated at 37°C in TK buffer with 0.02% Nonidet P-40 at a concentration of $800 \mu\text{g}$ virus protein per ml. This suspension was then assayed for inhibitor activity as described in Fig. 2 at a final concentration of $400 \mu\text{g}$ per ml. The totals after 6.25 h of incorporation were used to construct the curve shown in the figure.

TABLE 2 Effects of predigesting virions with trypsin on polymerase and inhibitor activities of Indiana VSV

	c.p.m.
Control virus 60 $\mu\text{g ml}^{-1}$	4,309
+ 65 $\mu\text{g ml}^{-1}$ ultraviolet-virus	3,387
+ 130 $\mu\text{g ml}^{-1}$ ultraviolet-virus	2,630
+ 260 $\mu\text{g ml}^{-1}$ ultraviolet-virus	1,463
+ 65 $\mu\text{g ml}^{-1}$ trypsinized ultraviolet-virus	3,009
+ 130 $\mu\text{g ml}^{-1}$ trypsinized ultraviolet-virus	2,303
+ 260 $\mu\text{g ml}^{-1}$ trypsinized ultraviolet-virus	1,629
Trypsinized virus 60 $\mu\text{g ml}^{-1}$	3,367

A 0.2 ml suspension of sucrose-purified Indiana VSV containing 2.5 mg virus protein per ml and 100 $\mu\text{g ml}^{-1}$ trypsin was incubated at 37°C for 2 h. The suspension was then passed through a 10 ml column of Bio-Gel A-5m, 100–200 mesh (Bio Rad), equilibrated with TK buffer. Control virus was handled in the same way except that trypsin was added after the 2 h incubation at 37°C. The transcriptase assays were carried out as in Table 1. The c.p.m. listed refer to incorporation per 30 μl samples after 3 h at 28°C. The kinetics of incorporation were similar to those shown in Fig. 2A for both control and trypsinized virus.

controlled, directly or indirectly, by some genetically determined virus component.

Initial investigations of the heat stability of the Indiana inhibitor gave the following results. Purified virions suspended in TK-buffered sucrose solution showed no loss of inhibitory activity when incubated for 2 h at 37°C. A temperature of 100°C for 1 min under the same conditions destroyed the inhibitor. If the virus was first disrupted with 0.02% Nonidet-P40 and incubated at 37°C as above, the inhibitor activity was lost with a half-life of approximately 5 min (Fig. 4), suggesting that the inhibitor irreversibly modifies a component of the polymerase under the conditions of the *in vitro* assay.

To determine whether the inhibitory activity is present on the surface of the virion, possibly as the spike protein,

FIG. 5 SDS gel electrophoresis of control and trypsinized Indiana VSV. Identical samples to those used in Table 2 were mixed with a small amount of high specific activity ^3H -amino acid (phenylalanine, tyrosine, and valine)-labelled Indiana VSV (supplied by Dr John Mudd). After processing as in Table 2, the samples were mixed with SDS and mercaptoethanol to 1% final concentration. They were then boiled for 30–60 s and dialysed against 10 mM sodium phosphate buffer, pH 6.8, 0.1% mercaptoethanol, 0.1% SDS, and boiled again. 0.3 ml samples were then subjected to electrophoresis in 7.5% acrylamide, 0.37% bis-acrylamide gels, in 0.1 M sodium phosphate, pH 6.8, 0.1% SDS buffer, for approximately 15 h at 90 V. The gels were crushed in a linear fractionator and the fractions counted in a Triton X-100 scintillation cocktail. A, control; B, trypsin-treated.

the Indiana virus preparation was digested with trypsin to remove the surface glycoprotein without affecting other virus components¹¹. The resultant skeleton was separated from trypsin by passing through a small column of Bio-Gel A-5m. This structure was then tested for remaining polymerase and inhibitory activity. Table 2 shows that approximately 80% of the polymerase activity and essentially all the inhibitory activity was retained in the skeleton structure. Parallel controls, in which a small amount of high specific activity ^3H -amino acid-labelled virus was added before trypsin digestion, were analysed by sodium dodecyl sulphate polyacrylamide gel electrophoresis. Fig. 5 indicates that more than 90% of the glycoprotein was removed. This experiment provides further evidence that the inhibitor is a virus-specific component, for trypsin treatment probably removes surface contaminants. Furthermore, the intact glycoprotein is ruled out as a candidate for the cause of the inhibitory activity.

We conclude from these data that purified VSV contains a specific inhibitor of the virus transcriptase. Two lines of evidence support this conclusion. First, the inhibition shows some degree of serotype specificity, and second, the inhibitor is present within the core structure of the virion produced by trypsin digestion. It is clear that in many studies where VSV transcriptase was measured *in vitro*, this inhibitory activity must have been present.

We can only speculate about the role of this activity *in vivo*. If the inhibitor is a VSV protein, as is most likely, the synthesis of this protein in the infected cell could lead to a switch from transcriptase to replicase activity. The common polymerase 'core' hypothesis for these two distinct activities is attractive as no new major proteins have been detected in infected cells apart from structural proteins^{12,13}. Another role for this activity could be to shut off host cell RNA synthesis.

It is interesting that Astell *et al.*¹⁴ reported that a reovirus structural protein, σ_3 , inhibits reovirus transcriptase when added back to subviral preparations lacking this protein. The relationship, if any, between these different inhibitors is not clear.

We thank Professor John Holland for facilities and for support and advice. We also thank LeFran Ciofalo and Estelle Bussey for technical assistance.

Structural homology of the glutamine amidotransferase subunits of the anthranilate synthetases of *Escherichia coli*, *Salmonella typhimurium* and *Serratia marcescens*

ANTHRANILATE synthetase (AS), the enzyme catalysing the initial reaction unique to tryptophan biosynthesis, chorismate + glutamine \rightarrow anthranilate, has been characterised from a number of bacterial genera¹. In *E. coli*²⁻⁴, *Salmonella typhimurium*⁵⁻¹⁰, and *Aerobacter aerogenes*¹¹, this enzyme and anthranilate-5-phosphoribosylpyrophosphate phosphoribosyltransferase (PRT) exist in a complex that also performs the second reaction of tryptophan biosynthesis, the conversion of anthranilate + 5-phosphoribosyl-1-pyrophosphate \rightarrow phosphoribosyl anthranilate. The AS-PRT complex of these bacterial genera is composed of two non-identical polypeptide components, each with a molecular weight of approximately 60-65,000. Component I of the complex can convert chorismate + $\text{NH}_3 \rightarrow$ anthranilate but cannot use glutamine as amino donor. Component II of the complex is bifunctional; it provides the glutamine amidotransferase (GAT) and the PRT activities. In *Serratia marcescens*¹²⁻¹⁴, *Bacillus subtilis*¹⁵⁻¹⁶, *Acinetobacter calcoaceticus*¹⁷⁻¹⁸, and various species of *Pseudomonas*¹⁹⁻²⁰, AS is not associated with PRT, which is a distinct protein. The AS of these bacteria consists of two non-identical subunits of different sizes. The large subunit, approximately 60-70,000 in molecular weight, functions as does component I of *E. coli*, *S. typhimurium* and *A. aerogenes* while the small subunit contributes the GAT activity. The molecular weights of the GAT subunit of *S. marcescens*^{12,14}, *Pseudomonas putida*^{19,20}, *B. subtilis*¹⁵, and *A. calcoaceticus*¹⁸ have been estimated to be 21,000, 18,000, 16,000 and 14,000 respectively. The PRT of *S. marcescens* has a molecular weight of 45,000, which is smaller than that of component II of *E. coli* and *S. typhimurium* by an amount equivalent to the molecular weight of a GAT subunit¹⁴.

The two functions of the component II of *E. coli* and *S. typhimurium* have been shown to be associated with different segments of the polypeptide chain. Proteolytic digestion of either the component I-component II complex

of *E. coli* and *S. typhimurium*⁹ or purified component II of *S. typhimurium*²¹ destroys PRT activity, but produces a component II fragment with GAT activity which is similar in size to the GAT subunit of *S. marcescens*. Genetic and mutational studies have further indicated that the amino terminal third of the component II of *E. coli*²² and *S. typhimurium*²¹ is responsible for the GAT activity while the remaining two thirds of the polypeptide provides PRT activity^{21,23}.

It has been suggested^{12,14,21} that the bifunctional component II of *E. coli*, *S. typhimurium* and *A. aerogenes* arose by the fusion of two genes, one coding for a GAT and the second coding for PRT. To examine this possibility, we have isolated and compared the amino terminal sequences of the GAT subunit of *S. marcescens* and the component II of *E. coli* and *S. typhimurium*.

For ease in purification and subsequent subunit separation, we isolated the GAT portion of component II of *E. coli* and *S. typhimurium* from partial proteolytic digests of intact component I-component II complexes. As indicated below, the amino terminal sequence of the GAT portion of the component II of *E. coli* is identical with that of intact component II of this organism. Presumably this is also true of *S. typhimurium*. The AS of *S. marcescens* was isolated intact and the subunits then separated. The details of the purification of the component II fragments and the *S. marcescens* complex and subunits will be described elsewhere. On the basis of SDS gel electrophoresis analyses we estimate that the molecular weights of the component II fragments of *E. coli* and *S. typhimurium* are 23,000 while that of the GAT subunit of *S. marcescens* is 21,400. The molecular weight of the component II fragment of *S. typhimurium*^{9,21} had previously been estimated as 24,000 and that of the GAT subunit of *S. marcescens*¹² as 21,000.

Automatic Edman degradation of the purified polypeptides was performed with a Beckman sequencer²⁴. Phenylthiohydantoin-amino acids were identified by gas-liquid chromatography²⁵ and (or) amino acid analysis²⁶ after hydrolysis of phenylthiohydantoin-derivatives with HCl or HI. The amino acid sequences of the component II fragments of *E. coli* and *S. typhimurium* and the intact GAT subunit of *S. marcescens* deduced from several degradation runs are shown in Fig. 1.

Fig. 1 Comparison of the amino-terminal sequences of the component II fragments of *E. coli* and *S. typhimurium* and AS-GAT subunit of *S. marcescens*. Residues of the *S. typhimurium* or *S. marcescens* proteins which differ from those in *E. coli* are given, while identity to the *E. coli* residue is indicated by a dash (-). Automatic Edman degradation of the component II fragment of *S. typhimurium* was programmed for 52 cycles only, while 61 residues were sequenced with the proteins of *E. coli* and *S. marcescens*. The amino acid residue at position 47 in the *S. typhimurium* and *S. marcescens* sequences could not be identified.

(Details will be published elsewhere.) To establish that the sequences of the component II fragments are identical to the amino terminal sequences of intact component II, we performed fifteen steps of automatic Edman degradation on isolated, intact, component I-component II complex of *E. coli*. The sequence attributable to component II was identical to that of the component II fragment.

It is evident from the alignment in Fig. 1 that the three sequences are homologous. The sequences of *E. coli* and *S. typhimurium* differ from that of *S. marcescens* by 23% (14/60 residues) and 27% (14/51 residues), respectively. It can also be seen that the sequences are in the same register throughout the 51 residue region compared, and that all three begin with the identical sequence of 8 residues. In view of these similarities it seems likely that the genes for the three GAT regions have homologous nucleotide sequences in the regions coding for the amino terminal segment of the respective polypeptides. Thus, it is highly probably that the GAT region of the bifunctional component II polypeptide of *E. coli* and *S. typhimurium* had the same evolutionary origin as the GAT subunit of the AS of *S. marcescens*. Functional homology of the GAT subunits of *E. coli* and *S. marcescens* is demonstrated by the observation that the GAT subunit of the latter species will complement *E. coli* component I to form an active hybrid molecule that can use glutamine as an amino donor¹⁴. In some organisms, for example *B. subtilis* and *A. calcoaceticus*, in which AS contains a small GAT subunit and is not associated with PRT, the GAT subunit appears to participate in a second biosynthetic reaction, that of *p*-aminobenzoate formation^{19,18}. It is not known if this is also true of the GAT subunit of the AS of *S. marcescens*. In view of all these observations, we can hypothesize, in agreement with earlier suggestions^{12,14,21}, that the evolutionary path resulting in the development of the bifunctional component II of *E. coli* and *S. typhimurium* was as follows. In an ancestral organism tryptophan biosynthesis preceded with NH₂ rather than glutamine as amino donor in anthranilate formation. Subsequently a GAT subunit, perhaps involved in *p*-aminobenzoate synthesis, acquired the ability to complex with a polypeptide analogous to AS component I, thereby permitting the use of glutamine, a more suitable amino donor. Then a copy of the gene for this GAT subunit was translocated into a tryptophan operon, adjacent to the gene coding for PRT. Coincident with the integration event, or later, the GAT and PRT genes became fused.

Two additional observations may be cited which lend support to some of the stages in the above scheme. First, in *E. coli*²⁷ it seems that there is a distinct gene for the GAT subunit of the *p*-aminobenzoate synthetase complex. Second, the GAT region of the gene coding for component II of *E. coli* is not essential for anthranilate formation^{23,28,29}. This suggests that addition of glutamine-utilizing activity to AS simply increased the efficiency of conversion of chorismate to anthranilate rather than providing the ability to perform a new, essential biosynthetic reaction.

It is not yet known whether the structural gene for the GAT subunit of the AS of *S. marcescens* is in the same operon as the structural genes for either the large subunit of AS, or for PRT¹⁴. In *B. subtilis* the structural gene for the small GAT subunit is unlinked to a single operon containing the genes for all the other proteins involved in tryptophan biosynthesis¹⁹. In *A. calcoaceticus* the structural gene for the GAT subunit is in a gene cluster also containing the genes for PRT and indole glycerolphosphate synthetase¹⁷. This gene cluster is not linked to the structural genes for any of the other proteins of tryptophan biosynthesis¹⁷. In *E. coli* and *S. typhimurium* all the genes are in one operon and the gene for component II follows immediately after the gene for component I, with the genetic region specifying the GAT portion of component

II, the amino terminal third of this polypeptide, closest to the gene for Component I^{5,21,22}.

It should be noted that the fusion of two structural genes with the retention of both enzyme activities has been demonstrated in studies with the histidine operon of *S. typhimurium*³⁰. Both fused and separate forms of functional polypeptides occur for other reactions of tryptophan biosynthesis e.g., in *E. coli*³¹⁻³³, *S. typhimurium*³³, *A. aerogenes*³³ and *S. marcescens*^{34,35}, phosphoribosylanthranilate isomerase and indoleglycerol phosphate synthetase activities are associated with a single polypeptide chain while in *A. calcoaceticus*¹⁷, *B. subtilis*³⁶ and *Pseudomonas putida* these activities reside in separate polypeptide chains.

A final point seems pertinent. The postulated series of evolutionary stages—from no GAT, to one GAT participating in two pathways, to two GATs, each specific for a pathway, can be considered analogous to the evolution in higher organisms of multiple genes coding for functionally and structurally similar proteins.

These studies were supported by grants from the US National Science Foundation and the US Public Health Service. C. Y. is a career investigator of the American Heart Association. We thank Howard Zalkin for his advice concerning the purification of the various anthranilate synthetases.

DNA Repair Monitored by an Enzymatic Assay in Multinucleate Xeroderma Pigmentosum Cells after Fusion

XERODERMA pigmentosum is a rare cutaneous disease of man displaying an autosomal recessive pattern of inheritance¹. The most conspicuous clinical symptom exhibited by homozygously afflicted individuals is hypersensitivity of the skin to solar radiation. Typically, the disorder eventuates in a high incidence of multiple carcinomas and frequently becomes terminal after the onset of metastatic epithelioma². Two clinical syndromes characterise the disease: (i) the more common classical form manifested solely by the cutaneous abnormalities and (ii) the De Sanctis-Cacchione (DSC) syndrome in which severe neurological complications, including mental retardation, accompany the skin malignancies².

Ultraviolet radiation ($\lambda < 320$ nm) induces cyclobutyl dimers between adjacent pyrimidines in the DNA of human cells. Cumulative evidence³ indicates that these otherwise deleterious photoproducts are removed from cellular DNA by an excision-repair process. The repair mechanism probably proceeds by the following sequence of enzymatic steps: (i) intrastrand incision proximal to the photoproduct; (ii) excision of the lesion perhaps within an oligonucleotide; (iii) repair replication to fill in the resulting single-strand gap, and (iv) strand rejoining³. Excluding several unexplained cases^{4,5}, primary fibroblasts derived from many genetically unrelated patients with either form of xeroderma pigmentosum are deficient in the excision repair of ultraviolet-induced damage^{3,6-9}. By analogy to the well documented excision-repair properties of ultraviolet-sensitive bacteria, the primary molecular defect in xeroderma pigmentosum most likely impairs the functioning of an ultraviolet-specific endonuclease¹⁰⁻¹³—the human analogue of the repair enzyme mediating the initial incision reaction in the bacterium *Micrococcus luteus*¹⁴.

In spite of an apparent obstruction at the same stage in repair, the genetic defects in the two clinical forms of xeroderma pigmentosum are complementary. Using somatic cell hybridisation, de Weerd-Kastelein *et al.*¹⁵ demonstrated that in binuclear cells containing one nucleus from each clinical form, DNA repair returns to that found in normal, repair-proficient cells. Thus, the ultraviolet-induced response is normal only when the binuclear cells possess a heterozygous combination of nuclei. To gain further insight into the fidelity of complementation, particularly at the biochemical level, we have used an *in vitro* enzymatic assay¹² to follow the disappearance of dimer-containing sites from the DNA of ultraviolet-damaged, multinucleate heterokaryons of xeroderma pigmentosum strains. The rationale behind the assay is the selective ability of an ultraviolet-specific endonuclease purified from *M. luteus* to produce single-strand scissions at sites containing pyrimidine dimers (referred to as nuclease-susceptible sites) in DNA extracted from ultraviolet-damaged cells.

As strongly suggested by inferential evidence¹², the assay monitors the presumed initial incision event. Use of this assay in combination with one measuring a late step in repair (that is, repair replication) may therefore permit us to detect in xeroderma pigmentosum hybrids any peculiarities in the excision-repair process stemming from the occurrence of genetic complementation.

The experiments reported here were performed with three human strains: AH⁹, established from a healthy volunteer; XP4RO derived from a classical xeroderma pigmentosum patient and XP25RO¹², procured from a De Sanctis-Cacchione donor. Monolayer cultures of primary fibroblasts were cultured at 37° C in Roux flasks containing thymidine-free F12 medium¹⁶ supplemented with 15% (v/v) foetal calf serum (Gibco). When required, radionuclides were incorporated into endogenous DNA by incubating cultures for 36–48 h in growth medium containing either 0.5 $\mu\text{Ci ml}^{-1}$ ³H-methyl thymidine (specific activity 2 Ci mmol⁻¹) or 1.0 $\mu\text{Ci ml}^{-1}$ 2-¹⁴C-thymidine (specific activity 53 mCi mmol⁻¹). (Both radiochemicals were purchased from the Radiochemical Centre, Amersham, Great Britain.)

Multinucleate cells were formed according to the procedure of Harris and Watkins¹⁷. Trypsinised cells of the two chosen strains were mixed in a 1:1 ratio at a final concentration of 2×10^6 cells per ml and incubated with ultraviolet-inactivated Sendai virus (final titre 500 haemagglutinating U ml⁻¹). This mixture was kept for 4 min at 4° C and after shaking at room temperature incubated for 20 min at 37° C. The fused fibroblasts were then seeded in Falcon Petri dishes (diameter 9 cm, each dish receiving the equivalent of 2×10^6 single cells) and incubated overnight at 37° C.

All subsequent procedures including those pertaining to (i) the administration of far ultraviolet light (chiefly 254 nm radiation; incident exposure rate 9 ergs mm⁻² s⁻¹); (ii) the enzymatic assay to monitor the disappearance *in vivo* of dimer-containing sites from cellular DNA, and (iii) ultraviolet-induced repair replication as measured by isopycnic centrifugation in sodium iodide gradients, were performed as described in detail earlier^{12,18}.

Incubation of ultraviolet-irradiated cultures for selected periods before performing the *in vitro* enzymatic assay enables us to trace the time course for the disappearance of nuclease-susceptible sites from the DNA of XP4RO/XP25RO hybrids and thus determine whether genetic complementation occurs at the presumed initial step in excision repair. The results of such an experiment are presented in Fig. 1. Fused cultures containing XP4RO/XP25RO heterokaryons can indeed rid their DNA of nuclease-susceptible sites; for example, after exposure to 125 ergs mm⁻² of germicidal light ~35% of the sites initially produced have been removed in 15 h while a smaller percentage—up to 20%—is eliminated during the same interval following an incident fluence of 250 ergs mm⁻². In sharp contrast, non-complementary preparations of XP4RO/XP4RO and XP25RO/XP25RO, like the corresponding unfused cell cultures¹², are at most only marginally proficient at attacking these sites containing pyrimidine dimers. It would appear, however, that the capacity for eliminating the sites from ultraviolet-damaged DNA has only partially returned after cell fusion of XP4RO was XP25RO; that is by the fifteenth hour after irradiation with 125 erg mm⁻² the xeroderma pigmentosum hybrid population has removed ~50% of those eliminated by normal cells. This intermediary level of site removal observed in the XP4RO/XP25RO hybrids is in excellent agreement with the percentage of the total nuclei in the same fused cultures present in multinucleate cells (that is ~55%). And since the enzymatic assay monitors not just the complementary heterokaryons but rather the entire cell population (also comprising mononucleate unfused cells and non-complementary fused ones containing two or more nuclei derived from the same strain), it seems reasonable to conclude that within the sub-population of XP4RO/XP25RO heterokaryons the ability to execute site removal has been restored to that proficiency displayed by normal cells.

Fig. 1 Relative rate of disappearance of nuclease-susceptible sites from the DNA of various fused human cultures after exposure to measured fluences (*a*, 125 ergs mm⁻²; *b*, 250 ergs mm⁻²) of ultraviolet radiation. Tritium-labelled cells of two selected strains were artificially fused as were two parallel ¹⁴C-labelled preparations. After incubation overnight 254 nm light was administered to the ³H-labelled hybrid cultures; immediately thereafter both the ultraviolet-damaged and the undamaged cultures were incubated in pairs for requisite times. The two types of radioactive cells were collected, pooled, and mixed thoroughly before cell lysis and *in toto* extraction of the irradiated and un-irradiated DNA. Two aliquots of the purified DNA were next incubated under conditions described before¹², one sample in the absence and the other in the presence of the ultraviolet-specific endonuclease from *M. luteus*. The number of nuclease-susceptible sites in the ultraviolet-injured DNA was determined retrospectively by sedimenting the two incubated DNA samples through alkaline sucrose gradients (40,000 r.p.m. at 20° C for 150 min in a SW 50.1 rotor). Finally the ensuing DNA profiles were analysed by a digital PDP8/1 computer to quantify the incidence of single-strand scissions directly attributable to endonucleolytic attack by the *Micrococcus* enzyme. (See ref. 12 for details concerning this computation.) The data for each curve were normalised by expressing the number of sites detected in the incubated samples as a percentage of the value (taken as 100%) found in the corresponding un-incubated sample. Each experimental point is the arithmetic mean of at least two independent determinations. Combinations of fused strains: ●, AH/AH; ○, XP4RO/XP25RO; ▲, XP4RO/XP4RO; △, XP25RO/XP25RO.

Self-hybridisation of a single strain (that is XP4RO to XP4RO) does not noticeably alter the repair properties of human fibroblasts. In unfused cell cultures the repair-proficient AH strain displays two-component kinetics for site removal at fluences of 65 and 125 but not at 250 erg mm⁻² (ref. 12), but in fused cell populations of AH these kinetics are also readily

demonstrable at 250 erg mm⁻² (Fig. 2). Although these discrepancies are of little relevancy to the interpretation of our data, they suggest a difference in the general morphological geometry of the fibroblasts after heterokaryosis. In comparison with the mononucleate cells, the fused cells, particularly those of high multinucleicity, attach but do not spread out on the Petri dish to the same degree before ultraviolet irradiation with the result that the effective biological fluence (measured retrospectively by the enzymatic assay) is consistently less than the calibrated incident fluence. This dosimetrical discrepancy presumably reflects partial shielding of nuclei by various cellular constituents absorbing 254 nm radiation.

In the same experiment we also studied complementation between strains representing the classical xeroderma pigmentosum and the DSC syndromes by assessing in the fused cell populations the magnitude of repair replication. This indicator of repair activity is interpreted to reflect the cumulative occurrence of the third step in excision repair in which single-strand 'repair patches' are inserted at infrequent intervals along the damaged DNA molecule⁶.

Fused preparations of normal AH cells served to simulate hybrids in which the extent of complementation was maximal while hybrid cultures of XP4RO/XP4RO and XP25RO/XP25RO were assayed to establish the residual level of repair exhibited by each XP strain in the absence of complementation. Figure 2 clearly demonstrates that XP4RO and XP25RO cells are considerably more proficient at repair replication when they are combined in multinucleate heterokaryons than when self-fused in homokaryons. As suggested above to account for the partial restoration of site

Fig. 2 Relative levels of DNA repair replication in artificially fused human fibroblasts as a function of incident ultraviolet fluence. After cell fusion and incubation overnight, the unlabelled cultures were grown in BrUdR (2 μg ml⁻¹) and FdUdR (10⁻⁶ M) for 2 h, exposed to indicated fluences of 254 nm radiation, and immediately labelled with ³H-methyl TdR (10 μCi ml⁻¹), BrUdR (2 μg ml⁻¹), FdUdR (10⁻⁶ M) and hydroxyurea (10⁻³ M) for an additional 3 h. The DNA was extracted *in toto* from each sample and centrifuged to equilibrium in neutral NaI gradients (38,000 r.p.m. at 20° C for 44 h in a Type 40 fixed-angle rotor). The isopycnic gradients were generated and analysed to measure the amount of repair replication (expressed as specific activity, that is, c.p.m. μg⁻¹ DNA, in DNA of normal density). Combinations of fused strains: ●, AH/AH; ○, XP4RO/XP25RO; ▲, XP4RO/XP4RO; △, XP25RO/XP25RO.

removal in the same preparations, the fractional amount of repair replication detected in the XP4RO/XP25RO hybrid cultures compared with that found in normal cells is an effect ascribed to the fusion condition in which only a fraction of the nuclei are present in multinucleate heterokaryons. Hence, in accord with similar studies reported elsewhere^{15,19}, after artificial union classical xeroderma pigmentosum and DSC strains mutually compensate for their respective genetic deficiencies.

Our results strongly suggest that as a result of genetic complementation multinucleate hybrid fibroblasts of XP4RO and XP25RO, human strains derived from classical xeroderma pigmentosum and DSC donors, respond to insult from ultraviolet radiation by executing *bona fide* excision repair with complete fidelity. These heterokaryons seem to exhibit normal kinetics for both the disappearance of nuclease-susceptible sites and repair replication, parameters probably measuring initial and late steps in excision repair. Furthermore, there is no rampant accumulation of single-strand scissions in the DNA of the damaged hybrid cultures during post-radiation incubation, as the incidence of strand breaks in ultraviolet-damaged DNA from incubated as compared with non-incubated samples was negligible. The most reasonable interpretation of our data is that the two clinical forms of xeroderma pigmentosum reflect mutations in different genetic complementation groups coding for the initiation of excision repair.

Thanks are extended to Drs R. A. Oosterbaan and H. L. Heijneker for the ultraviolet-specific endonuclease. This research was sponsored in part by a Post-doctoral Fellowship to M. C. P. from the Medical Research Council of Canada.

Measurement of Defects in Ultraviolet-irradiated DNA by the Kinetic Formaldehyde Method

ULTRAVIOLET irradiation of DNA converts a portion of the adjacent pyrimidine bases into cyclobutane dimers of the form $\hat{C}\hat{C}$, $\hat{C}\hat{T}$ and $\hat{T}\hat{T}$ ¹. As a consequence, hydrogen bonding and base stacking at these sites are disrupted, and localised denatured regions may appear. (Ultraviolet-induced denaturation has been reviewed in ref. 2.) Treatment of DNA with formaldehyde results in a preferential reaction at these denatured sites (or defects) because formaldehyde reacts only with free but not hydrogen-bonded amino groups³.

The theory developed by Trifonov *et al.*⁴ and Lazurkin *et al.*⁵ called the kinetic formaldehyde method (KF method), relates the rate of the reaction of formaldehyde with DNA to the concentration of defects in the DNA. Since formaldehyde unwinds the DNA as it reacts, the rate of reaction can be followed by determining the change in helicity from the change in the absorbance A_t at some time t , where

$$\theta = (A_{t_{final}} - A_t) / (A_{t_{final}} - A_{t_{initial}})$$

in which $A_{initial}$ and $A_{t_{final}}$ are the initial and final absorbances respectively. The relationship between θ and t is given by

$$(-\ln \theta) / t = 2cv + pv$$

where c is the concentration of initial defects per base pair, v is the velocity of unwinding at a defect site, and p is the rate constant for the initiation of new defect sites. A plot of $(-\ln \theta) / t$ against t gives a straight line with slope pv and intercept of $2cv$ on extrapolation to $t=0$. The initial rate of unwinding is defined as the intercept, $I=2cv$.

Defects can be single or double strand chain breaks or pyrimidine dimers. Experimental evidence shows that v is the same for both single and double strand breaks⁶. Little direct evidence, however, is available to support the basic assumption made in those studies that v for pyrimidine dimers is the same as for chain breaks, and the assumptions made in calibrating the KF method for pyrimidine dimers have been criticised².

Shafranovskaya *et al.*⁶ showed that for ultraviolet (254 nm) fluences $>10 \text{ J m}^{-2}$ the rate of formaldehyde reaction with irradiated DNA was six times slower than expected on the basis of numbers of dimers present in the DNA. The result was interpreted in terms of clustering of the dimers such that six dimers, for example, would be expressed as a single defect site. The origin of such clustering was proposed to be long range energy transfer (over as many as several thousand base pairs) resulting in preferential de-excitation at or near the site of an initially formed pyrimidine dimer, which serves to block further migration of the energy. An alternative possibility is that a break and a dimer are not equivalent sites, because of the constraints in unwinding an unbroken helix, and hence react with formaldehyde at very different rates.

We have designed experiments to test the assumption used by Shafranovskaya and coworkers that dimer and chain break defect sites react with formaldehyde at the same rate. To do so we used ultraviolet-endonuclease to convert pyrimidine dimer sites into chain breaks. This enzyme recognises pyrimidine dimers and makes nicks at the dimer sites⁷⁻⁹. A comparison of the rates of formaldehyde reaction before and after enzyme treatment should demonstrate any differences between the velocity of unwinding, v , associated with dimers and with chain breaks.

Tritium-labelled DNA was isolated from *Escherichia coli* B3 by the method of Marmur¹⁰ and dissolved in 0.01 M phosphate buffer, pH 7. Irradiation was done with the output (mostly 254 nm) from a 15-W low-pressure mercury lamp, in some cases in the presence of 0.03% H_2O_2 to produce chain breaks. Photolysis of H_2O_2 occurs with a quantum yield of unity, creating hydroxyl radicals which in turn make single strand

Table 1 Kinetic Formaldehyde Analysis of DNA containing Chain Breaks and Dimers

Ultraviolet fluence (J m ⁻²)	H ₂ O ₂	M _w (daltons × 10 ⁻⁶)	Breaks per base pair (× 10 ³)	UT/T (× 10 ²)	TT/T (× 10 ²)	PyPy per base pair (× 10 ³)	I (min ⁻¹ × 10 ³)	V = I/2C (min ⁻¹)
0	+	7.2	0	—	—	—	0	0

2,500	—	—	—	0.6	4.4	12.8	7	0.27

DNA was irradiated with 254 nm ultraviolet light in the presence, or absence of 0.03% hydrogen peroxide. Molecular weights were determined by sedimentation in an alkaline sucrose gradient. Single strand chain breaks were estimated assuming $M_n = 0.5 M_w$ (M_n , number-average; M_w , weight-average molecular weight) and $(M_n^0/M_n) - 1 = \text{No. breaks per molecule}$ (M_n^0 , initial molecular weight). Defects per base pair were calculated assuming 1,500 base pairs per 10⁶ daltons. PyPy per base pair does not include CC. The intercepts (I) were determined by extrapolation of $(-\ln \theta/t)$ back to $t=0$; I for the unirradiated sample was $1.5 \times 10^{-3} \text{ min}^{-1}$, which value was subtracted from all the intercepts to give the values shown. In addition, the intercepts for the peroxide treated samples were corrected for the small contributions estimated to come from dimers produced during irradiation.

chain breaks in the DNA¹¹. Photoproduct yields and single strand chain breaks were determined as described previously¹². The rate of reaction with formaldehyde (2.53%) was measured at 255 nm and at 54° C with a Beckman DU equipped with a Gilford model 2000 spectrophotometer attachment. The initial absorbance (A_{initial}) of the solutions was measured immediately after adding formaldehyde. After 90 min at 54° C, the temperature was raised to 90° C for 10 min and the final absorbance (A_{final}) was measured. The absorbance data were treated as described by Trifonov *et al.*⁴ and Lazurkin *et al.*⁵ to obtain I , the initial rate of unwinding.

To convert pyrimidine dimers into chain breaks, the ultraviolet-endonuclease isolated from *Micrococcus luteus* (a gift from W. L. Carrier) was allowed to react with the irradiated DNA for 30 min at 37° C. The enzyme was removed from the DNA before the formaldehyde reaction by extraction with an equal amount of 24:1 chloroform:alcohol. The DNA was then dialysed, with three changes, for 24 h against 0.01 M phosphate buffer.

The rate of formaldehyde reaction with DNA irradiated to form dimers or photolysed with hydrogen peroxide to make chain breaks was determined, and the rates of unwinding, I , were obtained. A value of v , the velocity of unwinding per defect, was then calculated from the known concentration of defects (either chain breaks or dimers). As Table 1 shows, the average value of v for breaks was 2.2 min^{-1} which agrees well with the value 2.4 to 2.5 min^{-1} obtained by Trifonov *et al.*⁴ for sheared DNA. This value is about an order of magnitude greater than that obtained for dimers, as indicated in Table 1. The difference does not, however, rule out the possibility proposed by Shafranovskaya *et al.*⁶ that the lower velocity of unwinding for dimers reflects clustering of dimers in the irradiated DNA.

To test their hypothesis we first treated irradiated DNA with ultraviolet-endonuclease, to convert dimer sites into chain breaks, and then treated it with formaldehyde. As Fig. 1 shows, the enzyme-treated sample reacted considerably faster

Fig. 1 Decrease in helicity, plotted as $(-\ln \theta)/t$ of ultraviolet-irradiated DNA exposed to formaldehyde for increasing lengths of time. Samples were treated with endonuclease in order to convert pyrimidine dimer sites into chain breaks. Quantitative analysis of the data is presented in Table 2. Curve (1) 800 J m⁻² with endonuclease; (2) 400 J m⁻² with endonuclease; (3) 800 J m⁻² without endonuclease; (4) no ultraviolet, with endonuclease; (5) no ultraviolet, no endonuclease.

than the untreated sample as judged by the large difference in their intercepts at $T=0$. (Enzyme treatment alone did not affect the intercept, although there was an increase in the slope of the curve.) As Table 2 indicates, the number of breaks per base pair made by the enzyme treatment was 3.3×10^{-3} , as compared with the initial concentration of pyrimidine dimers, 3.1×10^{-3} . This result implies that enzyme treatment made a break at the site of every dimer. It is calculated from the intercepts that the velocity of unwinding at chain break defects is seven to eight times faster than at pyrimidine dimer sites. This

Table 2 Kinetic Formaldehyde Analysis of Irradiated DNA Before and After Treatment with Ultraviolet Endonuclease

Ultraviolet fluence (J m ⁻²)	Endonuclease	M _w (daltons × 10 ⁻⁶)	Breaks per base pair (× 10 ³)	UT/T (× 10 ³)	TT/T (× 10 ³)	PyPy per base pair (× 10 ³)	I (min ⁻¹ × 10 ³)

800	+	—	~6*	—	—	—	8.7

* Since the samples receiving 800 J m⁻² contained no radioactive label, these values are estimations based on extrapolations from this and previous work.

difference suggests strongly that the result reported by Shafranovskaya *et al.*⁶ is not due to clustering.

Our conclusion—that chain breaks and dimers react with different velocities—is not surprising as the structure of DNA in the vicinity of a defect containing a single strand break would be expected to be less organised than that around a site containing a dimer, at which the sugar-phosphate backbone is still intact. Hence, formaldehyde reaction would be more likely to occur at a chain break than at a dimer.

A similar conclusion regarding base damage caused by ionising radiation was reached by Poverennyi *et al.*¹³, who observed that gamma-irradiated DNA reacted at the same rate with formaldehyde as DNase-treated DNA containing the same number of single strand breaks. Since gamma-irradiated DNA contains 4.5 times as many damaged bases (as determined by the loss of absorbance) as chain breaks, they concluded that base damage makes a negligible contribution to the reaction of gamma-irradiated DNA with formaldehyde.

We thank W. L. Carrier for ultraviolet-endonuclease and R. B. Setlow for helpful comments. This research was sponsored by the US Atomic Energy Commission under contract with the Union Carbide Corporation.

Effects of Low-dose X-irradiation on Chromosomal Non-disjunction in Aged Mice

THE factors responsible for the increasing incidence of offspring with Down's syndrome in older women are a continuing subject of debate. The demonstration of a greater frequency of aneuploid embryos in old mice^{1,2} may open the way for further experimental studies of the causes of some types of chromosomally abnormal conceptuses.

Clinical evidence suggests that the effect of maternal X-irradiation on the incidence of mongoloid children is a relatively small one³. Yamamoto *et al.*⁴ have presented results which, they claim, demonstrate that the bivalents of aged mouse oocytes are more susceptible to environmental injury than those of young oocytes. There is a decline in chiasma frequency and a corresponding increase in univalent frequency with age in mouse oocytes at diakinesis^{5,6}. Yamamoto *et al.*⁴ suggest that a deficiency of chiasmata could have predisposed aged oocytes to chromosomal damage during the long dictyate stage of meiosis. They argue from their results that, whereas

there was no significant effect of low-dose X-irradiation on the ova of young mice, there were significantly more chromosomally abnormal ova produced in old mice compared to young mice after irradiation. They emphasise the further increase in aneuploidy in old treated mice compared to old controls ($P=0.0337$ and 0.0600 for one and two-tailed tests, respectively). From all this they deduce (wrongly in our opinion) that the age of the mouse significantly affects the susceptibility of oocytes to irradiation damage. It should perhaps be mentioned that in comparing such small incidences, relatively large samples are required if significant differences are to be detected.

Table 1 Effect of low-dose X-irradiation on chromosome complement of 10.5-d-old mouse fetuses

Group	Total No. fetuses	No. aneuploid fetuses	% aneuploid fetuses (P)
Young non-irradiated	149	2	1.34
Young irradiated	111	4	3.60
Old non-irradiated	156	10	6.41
Old irradiated	43	7	16.28

* From the results of Yamamoto *et al.*⁴.

We have re-examined the data of Yamamoto *et al.*⁴ (Table 1) for evidence of interaction between age and X-irradiation. The differential effect of irradiation on ova from young and old mice was tested by comparing the appropriate function of the percentages with its standard error⁷. The value obtained was $(16.28 - 6.41 - 3.60 + 1.34) = 7.61$, with a standard error of 6.29, certainly a non-significant deviation from zero. This finding was confirmed by partitioning the three degrees of freedom of the contingency table into an age, irradiation and interactive effect. The latter comparison was found to be non-significant.

Both these statistical procedures, aimed at testing the conclusions of Yamamoto *et al.*, use linear differences in the percentages, which at such low incidences could prove quite misleading. A more meaningful method would be to examine the proportionate increases apparently due to irradiation, resulting in this example in the very similar ratios of $16.28/6.41 = 2.54$, and $3.60/1.34 = 2.69$ for old and young mice respectively. We have concluded therefore that these results do not show evidence of an interrelation of maternal age and radiation treatment.

Aneuploid embryos found in this study included uniform monosomics and trisomics as well as mosaics. Uniform aneuploids probably arise through chromosomal non-disjunction at meiosis I or, less likely, meiosis II, whereas mosaicism is produced by two cell lines developing in a single zygote. In the analysis of Yamamoto *et al.*⁴ these anomalies were grouped together, a fact which makes their conclusions even more questionable. If the mosaic embryos are excluded the incidence of aneuploid embryos found in their data is still higher in old (2.5%) compared to young (0) non-irradiated females ($P=0.0672$). A closer examination of the results of Yamamoto *et al.*⁴ strongly suggests that the data from their earlier published results¹ have been used as controls for the current irradiation studies. Such a procedure seems highly questionable in view of possible differences in environmental conditions.

In view of these objections we consider that the differential effect of X-irradiation on young and old oocytes to be not proven.

New selective Giemsa technique for human chromosomes, C_a staining

AFTER the introduction of the quinacrine fluorescence method¹, several Giemsa staining techniques have been developed for karyotype analysis of human chromosomes. Pardue and Gall², originally noticed a denser staining of centromeric regions of chromosomes after *in situ* hybridisation of mouse chromosome preparations with mouse satellite DNA followed by Giemsa staining. This initial approach was modified by Arrighi and Hsu³ who omitted DNA hybridisation. Later, Sumner *et al.*⁴ left out treatment with RNase and HCl as well. Finally, McKenzie and Lubs⁵ treated chromosomes with HCl and 2×SSC only. These modified Giemsa procedures all produce densely stained regions of one or both chromosome arms close to the centromere. These C-band procedures also stain the secondary constriction of chromosome 1, 9 and 16, as well as the distal part of the Y chromosome. Satellites that stain brightly by Q-band techniques are also revealed by these methods.

Recent improvements of staining procedures have allowed an identification of particular chromosome areas. Among others Gagné and Laberge⁷ and Bobrow *et al.*⁸ have developed different techniques that selectively stain the secondary constriction of chromosome number 9.

Here I report a new banding technique which reveals two identical dots at the place of the centromere, one on each chromatid. The dots appear to have the same size on all forty-six human chromosomes (Fig. 1). This pattern may be termed C_a, for centromeric dots. The dots give the appearance of very densely stained and sharply delineated spheres. The

uniform size of the dots may suggest that they represent organelles associated with the spindle fibres. Prometaphase chromosomes tend to show a very narrow band instead of the separate dots, perhaps indicating that the centromere has not yet divided at this stage. The technique is specific for the centromeric regions, in contrast to other C-band treatments, that also give staining of the secondary constriction of chromosome 1, 9 and 16, the distal part of the Y chromosome, as well as satellites.

The procedure was as follows: human metaphase preparations were obtained by culturing heparinised whole blood, 0.2 ml per 3 ml 30% human inactivated AB-serum in Earle (MEM) medium. The culture was collected after 72 h and treated with colcemid (in a final concentration of 0.2 µg ml⁻¹) during the last 2 h. Hypotonic treatment followed, with 0.075 M KCl (5 min) at room temperature. The cells were fixated three times in methanol: acetic acid. The first time, the ratio of methanol: acetic acid was 9:1; the second time, 5:1, and the third time, 3:1. The cells were spread directly by a Carlsberg pipette on a wet glass surface at 13° C and air dried. Slides which had been stored for 1 week at room temperature were incubated in Earle's BSS medium (pH 8.5–9.0) at 85° C for 45 min. The slides were then stained in 1/25 Giemsa (Merck) in a 1/300 M buffered phosphate (pH 6.5) for 10 min. It seems very important to standardise the production procedure for chromosome preparation before heat treatment for C_a bands to be produced routinely. The culturing, hypotonic, and fixation treatment, as well as the age of the slide after preparation, do influence the banding pattern. The same parameters have also been found important in the case of the G, C and R-banding techniques⁹.

The physicochemical basis of this staining reaction is not yet understood. But it is known that the highly repetitive DNA found in areas of constitutive heterochromatin can be divided into various DNA families, differing in base composition, repetitiveness, and so on¹⁰. C_a bands possibly represent a specific DNA-protein complex which has been preserved after heat and alkali treatment.

I thank Mrs L. Olsen for technical assistance.

Relationship between DNA content of polytene chromosome bands and heterochromatization in *Drosophila*

THE variegated position effect is associated with chromosomal rearrangements involving heterochromatin (reviewed in ref. 1). In *Drosophila melanogaster*, cytological studies of the salivary gland chromosomes of strains carrying such rearrangements show that in some cells, the chromosome regions adjacent to broken heterochromatin lose their char-

10A and 7E	0.877	0.660	1.138	n.s.

Salivary gland squashes from female white prepupae cultured at 14°C were stained by the Feulgen method. Using a Vickers M85 scanning microdensitometer, the integrated absorbance at 570 nm of the selected chromosome regions was measured in six non-heterochromatised nuclei in each of four preparations, two from each genotype. A $\times 100$ Planapochromatic objective of NA 1.3 gave a flying spot of diameter 0.47 μ m in the specimen plane, and 4% glare was offset electronically. Measured areas were precisely demarcated with a variable rectangular masking frame, and the apparent absorbance of an identical area of background, set to 90% transmission, was subtracted from each experimental reading. Each region was measured six times and the mean recorded.

M: mean Feulgen-DNA content of region in relative units.

\bar{R} : mean of ratios obtained by dividing Feulgen-DNA contents of region by that of reference band in same nucleus. *r*: correlation coefficient of Feulgen-DNA contents of two regions. For each strain, *n* = 12.

* for genotypes, see text.

acteristic banded appearance and become heterochromatised. The extent of this morphological change varies from cell to cell, but it has been noted that heterochromatisation seems to terminate preferentially just short of relatively large deeply staining bands^{2,3}. This observation might be due to the fact that such bands are more readily visible, and hence more likely to be scored as euchromatin than smaller bands. The involvement of other factors is however suggested by the observation³ that heterochromatisation associated with a given inversion in two genetic backgrounds terminates with different frequencies adjacent to certain bands which were morphologically similar in the two strains. A factor which, it has been suggested⁴, may affect the progress of heterochromatisation is a prior change in the nucleic acid content of affected regions. Early measurements of nucleic acid content using ultraviolet photographic microdensitometry of whole bands⁴ or spot estimations of optical density⁵ yielded equivocal results. We decided to use scanning microdensitometry to investigate the possibility that the differences in extent of heterochromatisation observed in our strains might be related to the DNA content of the bands concerned.

The Feulgen-DNA content of one affected band, 10D1-2, (terminology according to Bridges⁶) was measured in the single and double inversion strains, *m^x;+* and *m^x;Rev^p*. To correct for variations in staining and polyteny, the Feulgen-DNA contents of bands 10A1-2 and 7E1-2 were used as internal standards: 10A1-2 lies within the region subject to position effect but shows the same response to heterochromatisation in both strains, and 7E1-2 is beyond the region of potential heterochromatisation.

The results are summarised in Table 1. Mean uncorrected Feulgen-DNA contents of bands did not differ significantly between the strains, although in the case of band 10D1-2 the decrease in the double inversion strain approached statistical significance. When standardised against either of the reference bands, the mean value for 10D1-2 was significantly smaller in the double than in the single inversion strain. These results were confirmed by analysis of covariance (10D1-2 and 7E1-2: $F(1/22) = 4.55$, $P < 0.05$; 10D1-2 and 10A1-2: $F(1/22) = 4.63$, $P < 0.05$). In the single inversion strain there was a significant correlation between the Feulgen-DNA contents of 10D1-2 and each reference band, while in both strains there was significant correlation

between the two reference bands. Thus in the double inversion strain band 10D1-2 showed a relative, and possibly an absolute, decrease in Feulgen-DNA content and also exhibited less related variation than in the single inversion strain. Measurements were also made of band 50A1-2, a euchromatic band within the *Rev^p* inversion; of band 80A1-2, a relatively well defined heterochromatic band at the base of chromosome 3L; and of part of the chromocentral region which corresponded morphologically as closely as possible in each nucleus. No strain differences were found at these sites.

Band 10D1-2 therefore seems to be unusual not only in its relation to termination of heterochromatisation but also in its Feulgen-DNA content. The coincidence of these peculiarities suggests that the apparent irregularity in progression of heterochromatisation along the chromosome is not merely an observational artefact, but rather a genuine phenomenon related to some biological property of the bands concerned. Since the DNA content of a prepupal chromosome band presumably reflects the replication behaviour of the band during embryonic and larval development, a causal connection between heterochromatisation and DNA replication seems plausible. It should be noted that the chromosomes selected for measurement were not heterochromatised. Our results indicate that an additional rearrangement not only affects variegation and heterochromatisation³, but also influences chromosome bands in (potentially heterochromatised) regions which are morphologically euchromatic.

It is tempting to speculate that a break in heterochromatin leads to a change in replication behaviour of some euchromatic bands in its vicinity, and that the progression of heterochromatisation, when it occurs, is affected by such changes.

Light-regulated guanosine 3', 5'-monophosphate phosphodiesterase of bovine retina

RETINAL rod outer segment (ROS) adenylyl cyclase activity seems to be light sensitive, implicating adenosine 3',5'-monophosphate (cyclic AMP) in photoreceptor function^{1,2}. Guanosine 3',5'-monophosphate (cyclic GMP) could also play a role in photoreceptor function since the synthetic (guanylyl cyclase)³ and degradative (cyclic GMP phosphodiesterase)⁴ enzymes are highly active in purified ROS. In particular the specific activity of guanylyl cyclase is higher in bovine photoreceptor structures than in any other tissue studied. This activity, however, is not influenced by illumination³.

To assess cyclic GMP formation in a more physiological system, we followed the formation of ³H-cyclic GMP from ³H-hypoxanthine in isolated intact cattle retina. In the presence of a phosphodiesterase inhibitor, no differences could be detected between illuminated and dark-adapted retinæ. By contrast, without the inhibitor, a much lower ³H-incorporation was observed after preillumination (Table 1).

TABLE 1 Formation of ³H-guanosine 3',5'-monophosphate from ³H-hypoxanthine by bovine retina

	c.p.m.g ⁻¹ retina	
	With SQ 20,009	Without SQ 20,009
Exp. 1		
Dark	4,040	3,490
Light	3,420	1,000
Exp. 2		
Dark	6,520	4,580
Light	6,280	740

Young bovine eyes were obtained from a slaughterhouse and dark-adapted for 2 h at 0° C. Subsequent operations were carried out in dim red light. The retinæ were preincubated for 30 min at 37° C in Krebs-Ringer-bicarbonate buffer (pH 7.4, continuously gassed with 95% O₂ - 5% CO₂). After prelabelling (60 min at 37° C) with 2.5 µM ³H-hypoxanthine (5 µCi per retina), the retinæ were washed by five successive transfers into 100 ml beakers and then distributed one by one into 10 ml Erlenmeyer flasks containing 3.5 ml Krebs-Ringer-bicarbonate buffer with or without 0.3 mM cyclic nucleotide phosphodiesterase inhibitor SQ 20,009 [1-ethyl-4-(isopropylidenehydrazino)-1H-pyrazolo-(3,4-b)-pyridine-5-carboxylic acid ethylester]. The retinæ were then either left in the dark (0° C), or illuminated at 0° C in 5 ms (unfiltered flash light having a maximum energy of 30 J, 10 cm above the incubation vessel). The final incubation (10 min at 37° C) was started immediately. The retinæ were collected by rapid filtration and homogenised in 8% trichloroacetic acid (TCA). TCA was extracted by ether and the ³H-cyclic GMP separated from other nucleotides by successive chromatography on aluminum oxide (1.5 g Al₂O₃, Woelm W200 neutral) equilibrated with 0.06 M Tris-Cl buffer, pH 7.5) and Dowex 1 × 8 (formate, 0.5 × 4.5 cm) columns. The Al₂O₃ columns were washed with 2 ml 0.06 M Tris-Cl buffer, pH 7.5, and cyclic GMP eluted with 2 ml 0.6 M Tris-Cl buffer, which was passed through the Dowex columns. After a wash with 6.5 ml 0.5 N formic acid the cyclic GMP was eluted with 3 ml 8 N formic acid. Unlabelled cyclic GMP had been added to the TCA extracts to correct for recovery (51-64%). If the Dowex eluate was treated with beef heart phosphodiesterase (Sigma), less than 5 % of the radioactivity originally present could be detected after a subsequent chromatography on Dowex 1 × 8. No radioactivity from added ¹⁴C-cyclic AMP was found in the cyclic GMP fraction.

The results are expressed as c.p.m. in ³H-cyclic GMP per g fresh weight. Values are the mean for two retinæ incubated in parallel, the single determinations differed from the mean less than ±12 %.

Although these values, uncorrected for the specific activity of GTP, by no means measured exactly the synthesis of cyclic GMP, they indicate that retinal cyclic GMP levels could be regulated by light-dependent changes in phosphodiesterase activity. In fact, the cyclic GMP phosphodiesterase activity of retinal homogenates incubated in the light was more than three times that of homogenates assayed in the dark (Table 2). But in accord with previous studies,¹ cyclic nucleotide phosphodiesterase activity of purified ROS was not light sensitive. As expected, illumination was without effect on brain phosphodiesterase.

These results might suggest that a phosphodiesterase localised elsewhere than in the ROS could be influenced by light. But 84% of total retinal cyclic GMP hydrolysing activity is associated with the outer segments prepared and tested in the dark (unpublished).

With cyclic AMP as substrate, a much smaller light activation was seen (Table 2). This result is in keeping with the observation that cyclic GMP is the preferred substrate for ROS cyclic nucleotide phosphodiesterase, whereas an activity with a low *K_m* for cyclic AMP is localised in other retinal structures^{4,6}.

TABLE 2 Effect of light on retina cyclic nucleotide phosphodiesterase

Preparation	nmol GMP formed/mg protein/min	
	Light	Dark
Bovine retina homogenate	29.0 ± 1.6*	8.5 ± 0.8*
Bovine rod outer segments	157	154
Rat brain homogenate	28.3	26.7
	nmol AMP formed/mg protein/min	
	Light	Dark
Bovine retina homogenate	9.3 ± 0.6†	6.3 ± 0.8†

Retinæ from dark-adapted young bovine eyes (1-3 h at 0° C) were homogenised by hand in 5 volumes (w/v) 0.25 M sucrose-10 mM Tris-HCl buffer, pH 7.5, and aliquots (600-800 µg protein) assayed⁵ for cyclic nucleotide phosphodiesterase activity with either 1 mM cyclic GMP or 1 mM cyclic AMP in diffuse room light or in complete darkness (5 min at 37° C). To exclude the possibility that the reaction might go further than to the corresponding nucleosides, ³H-GMP and ³H-AMP were incubated with retina homogenates. Their recoveries were not influenced by light and virtually identical with those of the ³H-nucleosides added at the end of the incubation (70-76% for guanosine and GMP, 64-66% for adenosine and AMP).

* Mean value for nine experiments ± s.e.m. (*P* < 0.01).

† Mean value for four experiments ± s.e.m. (0.05 > *P* > 0.01).

The light activation could be mimicked by adding bleached ROS preparation devoid of phosphodiesterase activity and shown to contain no protein other than opsin, by gel electrophoresis⁷. ROS, prepared as described elsewhere⁸, were extracted with 0.1% sodium dodecyl sulphate (SDS), which was removed by repeated washing. Such preparations, left in the dark or illuminated until 65% bleaching had occurred, were added to the cyclic GMP phosphodiesterase assay. There was no effect on retina phosphodiesterase activity determined in the light (Table 3). Addition of the bleached preparation, however, increased the dark activity almost up to the activity determined in the light. Unbleached rhodopsin had also a small stimulating effect on the dark activity, possibly due to the presence of some bleached rhodopsin. The rhodopsin preparations contain membrane-bound lipids including retinal. But all-trans retinal, which is released during bleaching, had no effect on cyclic GMP phosphodiesterase activity measured in light or dark if added in concentrations equivalent to the amount present in the rhodopsin preparations. Traces of bound SDS could have a stimulatory effect. The SDS should, however, exert its effect on both light and dark activity. Furthermore, brain and liver phosphodies-

TABLE 3 Effect of adding preparations of photoreceptor membranes on retinal cyclic GMP phosphodiesterase activity

Addition	nmol GMP formed/mg protein/min	
	Light	Dark
Dark-adapted ROS preparation	33.9	14.5
Bleached ROS preparation	33.8	32.6
Control	34.3	8.7

ROS purified as described previously,⁸ were extracted twice with 0.1 % SDS—10 mM Tris-HCl buffer (pH 7.5). The insoluble material was washed first six times with 0.25 M sucrose—10 mM Tris-HCl (pH 7.5) and finally taken up in the same buffer (1 mg protein ml⁻¹). One part of the preparation was illuminated for 5 min at 0° C (33 W tungsten lamp, distance 4 cm), the rest left in the dark. Spectrophotometric estimations⁹ showed that 65% of the rhodopsin was bleached in the light-exposed preparation and less than 10% in the dark-adapted one. Aliquots containing 30 µg protein were added to samples of a retina homogenate (650 µg protein) and cyclic GMP phosphodiesterase activity determined in diffuse room light or in complete darkness. Buffer only was added to the controls.

terases, though stimulated by low SDS, were affected neither by dark- nor by light-adapted preparations.

Cyclic nucleotide phosphodiesterase inhibitors have been shown to have a profound effect on frog¹⁰ and *Limulus*¹ photoreceptor potentials. Our data show that regulation of ROS phosphodiesterase activities could be also physiologically important, since retinal cyclic GMP phosphodiesterase activity was strongly influenced by light. The light effect was most probably dependent on the bleaching state of rhodopsin, since it could be mimicked by adding light-exposed ROS preparations devoid of phosphodiesterase activity, where all components soluble in buffer and low concentrations of SDS had been eliminated. The light-provoked decrease of ³H-cyclic GMP levels in incubated retinac, not seen after phosphodiesterase inhibition, suggests that light-dependent changes in cyclic GMP phosphodiesterase activity occur also in intact retinac.

Cyclic nucleotide phosphodiesterase of taste receptors has been shown to be activated by bitter taste stimuli¹¹. Activation of phosphodiesterase activity by the appropriate stimuli might be a general phenomenon for the function of sensory receptors.

Correlations between (Na + K)-ATPase, Ca-ATPase and cellular potassium concentration in cattle red cells

THE existence in erythrocytes of active, ATP-dependent Na-K exchange on one hand and of active, ATP-dependent outward transport of Ca¹⁻⁵ on the other raises the question whether two independent or one common system account for these functions. Inhibition of the Na-K system by Ca, although easily demonstrated, does not lend particularly strong support to the hypothesis of a common pathway for Na and Ca in active transport, because full activation of the Ca system⁶⁻⁹ is achieved by lower Ca concentrations than those required to inhibit Na+K-ATPase⁸ and because Epstein and Whittam¹⁰ have pointed out that the effect is due to competition between Ca-ATP and Mg-ATP for the substrate site and that competition between Ca and Na for the transport site is unlikely. The Na-K system is inhibited by cardiac glycosides whereas Ca transport and Ca-activated ATPase are not^{2,3,11} which seems to exclude a common site, but not necessarily a common protein. If alkali cation and Ca movements were mediated by the same membrane protein independent measurements of Na+K-activated ATPase and Ca-stimulated ATPase activity should positively correlate. K concentration in cattle red cells varies widely between animals^{12,15}, there is agreement as to the ability of these cells to pump Na and K¹³⁻¹⁷, and indications exist that different intensity of pumping accounts for the different K (and Na) content of the cells¹²⁻¹⁴. Cattle cells, therefore, seem suitable objects to study phenomena which might correlate with Na+K-ATPase.

Blood (100 ml) from healthy adult (above 2-yr-old) Simmental and Swiss Brown cows was prevented from clotting by adding approximately 17 U ml⁻¹ heparin (USP) and brought to the laboratory within a few hours. The cells were washed four times with a solution of (mM) 120 choline-Cl, 40 Tris-Cl, pH 7.4 in the cold. Na-free solution was chosen to avoid any possible Na-Ca exchange during washing. White cells were discarded. K in washed and packed cells was measured by flame photometry in the haemolysate (0.1 ml cells + 7.9 ml H₂O). For the measurement of cellular Ca the cells were diluted 1:4 with water, the mixture deproteinised with an equal volume of trichloroacetic acid (10%) and the supernatant made up to 50 mM LaCl₃ in another 1:2 dilution step to prevent interference of phosphate. Standards of CaCl₂ were made up in the same water and LaCl₃-solution and the samples were measured with an EEL atomic absorption flame photometer with scale expansion unit and recorder. Results were corrected for Ca contamination of trichloroacetic acid. The choline-washed cells were further washed twice with a solution of (mM) 150 NaCl, 5 KCl, 1 MgCl₂ and membranes were prepared from them according to Wolf⁷ as described earlier⁶. The membranes were kept frozen until used (36 h at most). Na+K-ATPase was measured as the ouabain-inhibitable fraction in a medium of (mM) 100 NaCl, 10 KCl, 4 MgCl₂, 0.5 tris-EGTA, 30 imidazole-Cl, pH 7.0 (at 37°C), 2 Mg-ATP, with or without ouabain 10⁻⁴ g ml⁻¹. Ca-ATPase was assayed in the following medium: (mM) 70 choline-Cl, 4 MgCl₂, 30 imidazole-Cl, pH 7.0 (at 37°C), 0.5 Ca-EGTA buffer (of 10⁻³M Ca²⁺ concentration) or 0.5 Tris-EGTA, 2 Mg-ATP and 10⁻⁴ g ml⁻¹ ouabain. The samples contained on average 1.47 mg protein in 2.5 ml, incubation time was 90 min and temperature 37°C. In six experiments Ca-ATPase was measured in the absence of Mg, Mg-ATP being replaced by Na-ATP. All samples were run in duplicates. P_i liberated and protein were measured as before⁶. Since high K cells are rare^{12,13} many animals were sampled for K content of cells and twenty-one specimens were selected such as to have all K concentrations about equally represented.

It was found that cellular Ca concentration is far below the Ca^{2+} concentration in blood plasma, much as was reported for human red cells^{18,19}. The average from thirteen

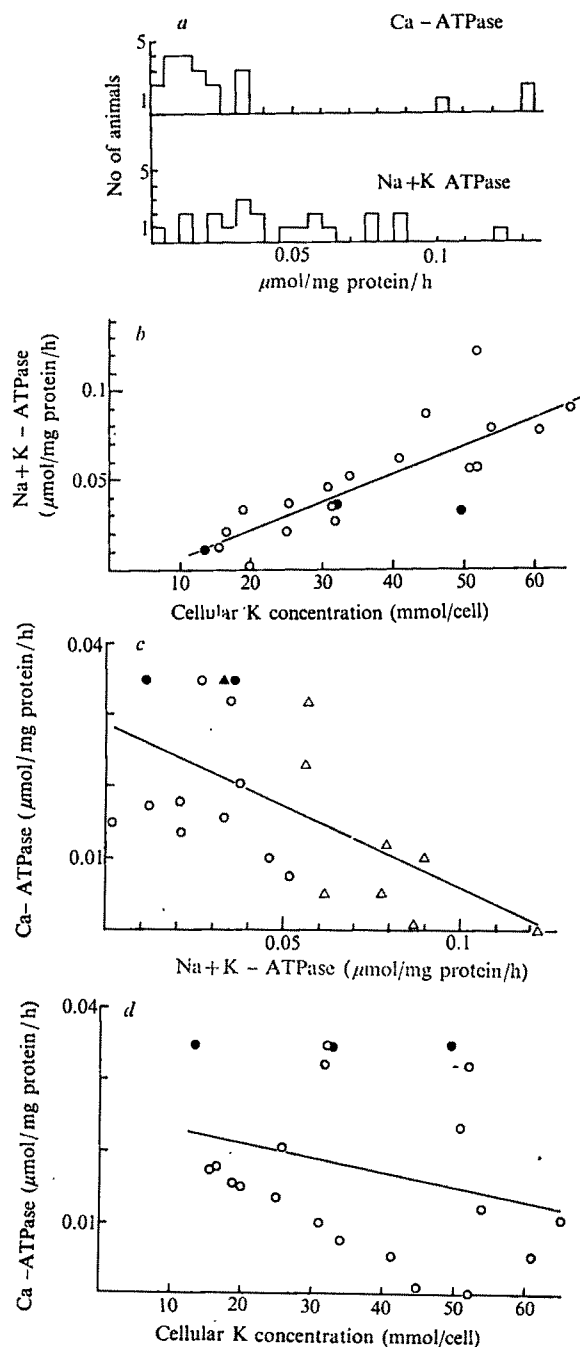

Fig. 1 Cellular K concentration, Na+K-ATPase and Ca-ATPase activity in erythrocytes of twenty-one cows. Ca-ATPase: difference between sample with 10^{-5}M Ca^{2+} and sample with 0.5 mM EGTA (medium: choline 70, imidazole 30, Mg-ATP 2, Mg 4, Cl 108 mM, ouabain 10^{-5} g/ml). Na+K-ATPase: difference between sample without and with ouabain 10^{-4} g/ml (medium: Na 100, K 10, imidazole 30, Mg-ATP 2, Mg 4, Cl 148 mM). pH 7.0, 37°C , 90 min. Cellular K concentration measured in fresh cells, washed with choline-Cl 120 mM, tris-Cl 40 mM, pH 7.4. a, b, c, d: Same data plotted differently. a: Frequency distribution of Na+K-ATPase does not peak, because animals were selected in order to have all K concentrations equally represented (compare with b). Notice three outliers in the Ca-ATPase values from the same animals. b, c, d: Each point represents 1 animal. b, $r = 0.819$, $P < 0.001$; c, $r = -0.588$, $P < 0.01$; d, $r = -0.272$, $P > 0.05$. Solid symbols = Ca-ATPase outliers (Ca-ATPase values corrected as described in text). c, Triangles = animals with K concentration in cells $> 40\text{ mmol l}^{-1}$ cells. Calculated regression lines and r values include all points shown.

animals was $0.024 \pm 0.003\text{ mmol l}^{-1}\text{ cells}$ (\pm s.e.m.). This is not due to the washing procedure since unwashed cells gave values similar to what was predicted on the assumption of virtually Ca free cells contaminated by 6–8% blood plasma. No correlation between cellular Ca content and Ca-ATPase activity of the corresponding membranes was found, which is not surprising, as it is well known that in human red cells total Ca is largely accounted for by Ca associated with the membrane and does not reflect intracellular Ca concentration^{18,19}.

Figure 1a shows the frequency distribution of the Ca-ATPase in twenty-one animals. The average, omitting the three outliers, was $0.0151 \pm 0.0024\text{ }\mu\text{mol per mg protein per h}$ (\pm s.e.m.) which is about 1/50 of what is found in human red cells under similar conditions. The outliers were 9.6 standard deviations or more away from the mean and were, therefore, omitted from the statistical evaluation or replaced by the highest value of the rest of the distribution (0.0348) as shown in Fig. 1 by solid symbols (C. P. Windsor, quoted in ref. 20.) Preliminary experiments indicated that the dissociation constant K_a of the enzyme for Ca^{2+} is of the order of 10^{-6}M . There is some Ca-stimulated activity in the absence of Mg. In six experiments this amounted to 14.3% of the total Ca-stimulated activity in the presence of Mg. This activity was not separated from the total in the statistical treatment.

Figure 1b shows that a close positive correlation exists between Na+K-ATPase activity and cellular K content. The calculated regression line extrapolates to the reasonable K concentration of 6 mmol l^{-1} cells at zero Na+K-ATPase activity. This is according to expectation and agrees with the accepted view that the Na-K pump is a major factor controlling cellular K concentration.

The main finding is illustrated in Fig. 1c. Ca-ATPase activity and Na+ATPase activity correlate negatively ($P < 0.05$ when the outliers for Ca-ATPase are omitted, $P < 0.01$ when they are reduced to $0.0348\text{ }\mu\text{mol mg}^{-1}\text{ h}^{-1}$ in a two-tailed test). Triangles represent samples which can be attributed with a high degree of probability to the class of animals with genetically determined high K cells in our breeds^{12,13}. Within this group the correlation coefficient (r) is -0.807 (with $P = 0.009$) when the outlier is reduced to 0.0348.

Figure 1d demonstrates that no significant correlation was found between Ca-ATPase activity and cellular K content. But when the partial correlation coefficient ($r_{D.bc}$) is calculated (eliminating the effect of the correlations b and c of Fig. 1), a positive correlation is revealed with $r_{D.bc} = 0.450$ and $z\sqrt{N-4} = 1.953$. For a two-tailed test

$$z\sqrt{N-4} = \frac{1}{2} \cdot \ln[(1+r_{D.bc})/(1-r_{D.bc})] \cdot \sqrt{N-4} > 1.96 \text{ for } P < 0.05$$

with N = number of points. This means that the positive correlation is just significant. Thus it seems not unlikely that the negative correlation between Na+K-ATPase and Ca-ATPase masks a positive correlation between Ca-ATPase and K content of the cells.

The negative correlation between Ca-ATPase and Na+K-ATPase makes the hypothesis of a single system for both improbable. Competition between alkali cations and Ca can be ruled out because Na+K-ATPase was assayed in the absence of Ca and Ca-ATPase was measured in the absence of Na and K (except for approximately 0.2 mM stemming from the membrane preparation) and in the presence of ouabain. No interpretation with respect to cause and effect can be offered for the negative correlation at present, but several possibilities might be considered. (1) The Na-K pump requires traces of Ca inside the membrane and the Ca pump removes Ca more effectively from the critical region than EGTA alone does. (2) A fixed number of molecules of an individual protein are synthesised in the maturing cell

and an unknown factor determines whether any one of these behaves as a Ca- or Na-K-pump site. (3) In the synthesis of two distinct pump proteins some step is common for both and limiting and the final assembly into structurally different complexes determines the functional use of the common part. (4) An unknown factor is inhibitory for one and stimulatory for the other of two distinct pumps.

The positive correlation between Ca-ATPase and K content of fresh cells might mean that a low intra-cellular Ca concentration facilitates maintenance of high intracellular K concentration. It is well known^{5,21-25} that a small increase in cellular Ca concentration renders human red cells leaky to K. The present finding might reflect this effect of intracellular Ca* and, therefore, could substantiate the view expressed by Gardos²¹ as early as 1958 that cellular Ca content might influence cellular K concentration not only under abnormal experimental conditions but also *in vivo*.

The help of Drs J. Anetzhof and G. Stämpfli who collected the blood and the advice from Dr M. Schafroth (Department of Mathematical Statistics) concerning the testing of a partial correlation coefficient are acknowledged.

* *Note added in proof:* This interpretation is doubtful, as a recent report (Jenkins and Lew, *J. Physiol., Lond.*, **234**, 41 (1973)) demonstrates the absence of the Gardos-effect in ruminant red cells.

Molecular weight of a D-glucose and L-histidine-binding protein from intestinal brush borders

We describe here a sugar and amino acid transport protein that has been isolated from a cell for the first time. It is

a homogeneous protein subunit from the mucosal brush border of hamster jejunum that is involved in the Na⁺-dependent binding of actively transported D-glucose and L-histidine. Its molecular weight was estimated to be 59,000 by Sephadex G-75 gel filtration¹, 56,000 by sodium dodecyl sulphate-acrylamide gel electrophoresis^{2,3}, and 50,934 by sedimentation velocity analysis^{4,5}. The presence of both D-glucose and L-histidine-binding sites on the same protein with a molecular weight of approximately 55,000 may account for some of the observed competitive inhibitory effects between active intestinal sugar and amino acid transport that have been reported⁶.

Our work is based on the results of many studies which have indicated that active transport of sugars and amino acids by the small intestine occurs within the brush border of the mucosal cell and requires sodium ions⁷⁻¹⁰. In an attempt to describe these absorptive mechanisms, we have shown that actively transported sugars and amino acids are preferentially bound to isolated brush borders^{11,12} and that both D-glucose and L-histidine require Na⁺ to bind to separate sites in a filamentous fraction of disrupted brush borders^{13,14}. Since the brush border is a digestive, as well as an absorptive organelle¹⁵, we have postulated that its core filaments act as a conduit for the Na⁺-dependent active transport of all monosaccharides and all amino acids which are primarily obtained from the hydrolysis of disaccharides and polypeptides on the plasma membrane facing the lumen¹⁴. The purpose of the study reported here was to solubilise the brush border fraction involved in the Na⁺-dependent binding of D-glucose and L-histidine, and determine its molecular weight.

Mucosal brush border filaments from hamster jejunum were prepared^{13,14} and labelled with ¹⁴C by incubation at 37° C for 30 min in either 0.1 μM of uniformly labelled ¹⁴C-D-glucose (288 mCi mmol⁻¹) or 0.5 μM of uniformly labelled ¹⁴C-L-histidine (240 mCi mmol⁻¹) in 25 mM Na₂HPO₄-NaH₂PO₄ buffer (pH 7.2), 10 mM MgCl₂, and 6 mM dithiothreitol (DTT). After the incubation period the suspension was centrifuged and the supernatant was removed. Then the filamentous precipitate was extracted with cold acetone. Most of the radioactivity remained in the insoluble precipitate indicating that the ¹⁴C-labelled compound was not bound to the lipid-soluble portion of the filaments. The acetone powder was solubilised by incubating the ¹⁴C-labelled material, at 25° C for approximately 12 h, in 1% SDS, 25 mM sodium phosphate buffer (pH 7.2), 10 mM MgCl₂, 6 mM DTT, and the same concentration of the ¹⁴C-labelled compound that was used in the binding experiment. Figure 1 illustrates a typical elution profile of this solution obtained by Sephadex G-75 gel filtration. In the experiment illustrated, ¹⁴C-D-glucose was bound within a sharp peak absorbing at 230 nm. Though there was some absorption before and after the peak it did not obtain any bound ¹⁴C-D-glucose. Free radioactive sugar appeared in the elution volume between 450 ml and approximately 550 ml. This was confirmed by control experiments in which only free ¹⁴C-D-glucose was placed on the column. Similar results were obtained when ¹⁴C-L-histidine was used as the binding compound. Although both ¹⁴C-D-glucose and ¹⁴C-L-histidine were bound within the same peak of absorbance, more ¹⁴C-D-glucose ($4.17 \pm 0.96 \times 10^{-8}$ mmol) than ¹⁴C-L-histidine ($1.95 \pm 0.07 \times 10^{-10}$ mmol) was bound per mg of protein as determined by four and three experiments, respectively. The amount of the ¹⁴C-labelled compound bound was calculated from its measured radioactivity and specific activity. Protein was determined by the Lowry *et al.* method using bovine crystalline serum albumin as standard¹⁶.

To verify that the isolated protein is the component involved in Na⁺-dependent binding of actively transported nutrients by the hamster jejunum, the denaturing SDS adhering to it had to be removed. This was accomplished by

Fig. 1 Elution profile from gel filtration of acetone extracted, SDS-solubilised brush border filaments labelled with ^{14}C -D-glucose in the presence of Na^+ ions. Before the solubilised material was placed on a Sephadex G-75 gel bed in a 2.6×100 cm column, it was diluted with 25 mM of $\text{Na}_2\text{HPO}_4\text{-NaH}_2\text{PO}_4$ buffer (pH 7.2) containing 10 mM MgCl_2 and 6 mM DTT to achieve a 0.1% SDS concentration, filtered with a $0.45 \mu\text{m}$ pore diameter filter, and centrifuged at 112,000 g for 2 h. The small amount of precipitate obtained after centrifugation was discarded. A 4 ml sample of the supernatant containing approximately 5 mg of protein were placed on the Sephadex G-75 gel filtration column eluted with 25 mM sodium phosphate buffer (pH 7.2) containing 0.1% SDS, 10 mM MgCl_2 , and 6 mM DTT. The void volume of the gel column was 140 ml. After the absorption of the eluant was read at 230 nm to detect peptide bonds, each 5 ml fraction was dried at 80°C in a vial. Then 15 ml of liquid scintillation fluid was added to each vial before it was counted in a Nuclear Chicago mark I liquid scintillation system. The peak in absorbance had bound $4.17 \pm 0.96 \times 10^{-8}(4)$ mmol of ^{14}C -D-glucose per mg of protein. An absorption spectrum of this peak was performed after it had been precipitated by 30% $(\text{NH}_4)_2\text{SO}_4$ and redissolved in 25 mM sodium phosphate buffer (pH 7.2). Absorption occurred at approximately 280 nm and 230 nm, demonstrating that the peak contained protein relatively free from other ultraviolet absorbing compounds. —, Absorbance; •••, D-U- ^{14}C -glucose.

dissolving the unlabelled, partially purified binding protein, obtained by precipitation with 30% $(\text{NH}_4)_2\text{SO}_4$, in 50 mM Tris-acetate buffer, pH 7.8, containing 6 mM DTT and 6 mM urea. This solution was passed through a SDS-removal column containing Dowex 1-X2¹⁷. The SDS-free effluent was then placed in the hollow bore fibres of Bio-Fiber 50 minibeaders obtained from Bio-Rad Laboratories to exchange 25 mM sodium, potassium or ammonium phosphate buffer, pH 7.2, for the Tris-acetate buffer and to remove urea. The buffer on the outside of the hollow fibres was replaced every 15 min for 1 h at 5°C . The last replacement contained $0.1 \mu\text{mol}$ of ^{14}C -D-glucose (uniformly labelled; 288 mCi mmol⁻¹). Diffusion of the ^{14}C -D-glucose across the fibre walls was then allowed to proceed for 1 h at 37°C . We had previously determined, in the absence of protein, that ^{14}C -D-glucose can reach a diffusion equilibrium under these conditions. After this incubation period, ^{14}C in 0.1 ml samples of the solutions inside and outside the hollow fibres were counted in a liquid scintillation system. The results from these studies demonstrated that ^{14}C -D-glucose was at a higher concentration within the hollow fibre compartment containing the binding protein only when Na^+ ions were present. When either K^+ or NH_4^+ were substituted for Na^+ in the phosphate buffer, ^{14}C -D-glucose was observed to be at the same concentration in both compartments. Therefore, the increase in ^{14}C -D-glucose within the protein compartment in the presence of Na^+ could only be attributed to the binding of this sugar to the isolated protein. The amount of sugar bound per mg of protein was similar to that observed in the absorbance peak from the Sephadex G-75 gel filtration column (Fig. 1).

Narcotic Receptor Sites in Morphine-dependent Rats

THE biochemical basis of the development of tolerance for and dependence on narcotic analgesics has been the subject of much speculation and experiment¹⁻⁶. Theories which try to account for these closely related^{4,7} phenomena can be grouped into three main classes: (1) the body reacts to narcotic drugs by increasing the rate at which they are destroyed or neutralised (by antibodies, for example) so that a smaller proportion of the total dose reaches the brain receptors²; (2) processes which are directly affected by the narcotic analgesics are circumvented or otherwise accommodated through an indirect physiological adaptation⁶; (3) a direct adaptation takes place in which the number of receptor sites for the narcotics is greatly increased, or their affinities greatly reduced so that large amounts of drugs are needed to fill the available sites and thus effect a response⁵. We wish to present data which effectively rule out this third possibility as a major factor in narcotic drug dependence and tolerance. We show that neither the number, nor the binding affinity, nor the specificity of narcotic receptor sites⁸⁻¹⁰ is changed in the morphine-dependent (and therefore also tolerant⁷) rat brain when compared with that of the normal animal.

Osborne-Mendel rats, 150–200 g, from the NIH colony, were used, mostly males, although one set of experiments involved females, with equivalent results. Morphine dependence was induced by implanting pellets containing 75 mg of morphine base plus CM cellulose carrier and binders^{7,11}, subcutaneously near the midline of the back just behind the ears¹². Light ether anaesthesia was used. This procedure induces clear-cut tolerance to and dependence on morphine, which is maximal

Fig. 1 The specific binding of ^3H -dihydromorphine to particulate fractions of rat brain homogenates prepared from control (○) and morphine-dependent (●) rats. The data are obtained by subtracting the amount of non-specifically bound ^3H -dihydromorphine, measured in the presence of 10^{-5} M morphine (a saturating amount) from the amount bound in the absence of unlabelled morphine. Each flask contained 0.5 mg of P_2 protein, 9 μmol Tris-HCl, pH 7.4, and ^3H -dihydromorphine (31,000 c.p.m. pmol^{-1}) in the amounts shown, in 1 ml of 0.32 M sucrose. The points shown are the average of two independent experiments each of which was performed with duplicate determinations.

after 72–96 h and declines slowly during the next few days¹². Spot checks on some animals 72 h after operation with an intraperitoneal injection of the antagonist naloxone (1 mg of the hydrochloride in 0.1 ml H_2O) showed that the animals carrying the morphine pellet went into almost immediate withdrawal^{12,13}, characterised by extreme hyperactivity, sensitivity to touch (manifest by squealing), wet dog shakes and diarrhoea. Control, sham operated, animals were unaffected by naloxone.

The animals were decapitated 72–84 h after implantation of the morphine pellet. Brains, without the cerebellum, were homogenized in 10 volumes of 0.32 M sucrose using twenty strokes of a loosely fitting Teflon-glass homogenizer. The homogenate was centrifuged at 1,000g for 10 min and the supernatant fraction was centrifuged at 10,000g for 10 min. The pellet (P_2)¹⁴ was suspended in the original volume of 0.32 M sucrose and diluted with 8 volumes of 0.32 M sucrose, 0.01 M Tris-HCl, pH 7.4, for assay. Brains of three to six rats were pooled after homogenisation in each of four independent experiments, all of which gave equivalent results.

Narcotic drug binding was studied with the aid of ^3H -dihydromorphine, specific activity 51.2 Ci mmol^{-1} (New England Nuclear Corp.). Brain homogenates or, more usually, the 10,000g particulate fractions P_2 (0.5 mg of protein in 900 μl of 0.32 M sucrose, 0.01 M Tris-HCl, pH 7.4), were incubated with ^3H -dihydromorphine in the presence and absence of unlabelled morphine (or other drug) at a concentration such that the specifically bound dihydromorphine was displaced by the unlabelled narcotics. After 10 min at 37° C, unbound radioactive material was removed by centrifugation at 19,000 r.p.m. for 10 min. The tube and surface of the pellet was washed with 1 ml of 0.32 M sucrose and the washed pellet, suspended in 1 ml of 1% Triton X-100, was assayed for radioactivity. All operations involving dihydromorphine were carried out in the dark or in a room illuminated with extremely dim, indirect daylight. At 10^{-9} M dihydromorphine, as in Figs. 2–4, approximately half the bound radioactivity was specifically bound in that it was displaced by low concentrations of narcotics but not by their inactive stereoisomers.

Residual morphine present in the P_2 fraction of the homogenate of the brains of morphine-treated animals was estimated after extraction by the method of Mulé¹⁵. The organic solvent extracts, after removal of the solvent, were dissolved in a small volume of methanol. Aliquots were assayed for morphine by measuring the amount of bound ^3H -dihydromorphine displaced in our standard binding assay compared with standard morphine solutions. The total amount (free and bound) of residual morphine present in the P_2 fraction, 0.5–1.5 pmol per mg protein, was such that its concentration was less than 10^{-9} M when diluted as in our standard assay. Such concentrations could not affect our results in any important manner. Furthermore, repeated washings of the P_2 fractions did not change our results.

Figure 1 shows the specific binding of dihydromorphine to brain P_2 fractions prepared from normal and morphine-dependent rats. The two sets of data, identical within experimental error, show that both the number and binding affinity of the morphine receptor sites are the same in the control and morphine-dependent animals. Although the data are expressed per mg of protein they are also valid per rat, since the size and protein contents of the brains of the control and morphine-dependent rats were approximately the same.

Specificity of binding was assessed by measuring ^3H -dihydromorphine binding (at 10^{-9} M) at varying concentrations of narcotic analgesics (and other drugs). In all cases, the brain particulate fractions of normal and morphine-dependent animals were indistinguishable with respect to their binding properties. Thus, Fig. 2 presents data showing the competition of morphine for the receptor site and shows the identity of the two types of brain preparations. The narcotic antagonist naloxone also competes in an identical manner for the specific narcotic receptor sites of morphine-dependent and control rats (Fig. 3) as does the anticholinesterase, eserine (Fig. 4).

These experiments provide evidence that morphine dependence (and therefore also tolerance^{4,7}) is not the result of an alteration in the number or of the nature of the specific receptor sites in the brains of rats. Thus, this class of theories cannot account for narcotic drug dependency. In corroboration is the fact that dependent animals, tolerant to large doses of narcotic drugs, still react vigorously to small doses of antagonists such as naloxone or nalorphine^{7,12}. These are believed to bind to the

Fig. 2 The displacement of bound ^3H -dihydromorphine from particulate fractions of rat brain homogenates by morphine. Open circles, control; filled circles, morphine-dependent animals. Each flask in this and the subsequent figures contained 0.5 mg of P_2 protein, 9 μmol Tris-HCl, pH 7.4, 1 pmol ^3H -dihydromorphine (31,000 c.p.m.), and the indicated concentration of unlabelled drug in a total of 1 ml of 0.32 M sucrose. The points are single values, and the binding indicated is per flask.

Fig. 3 The displacement of bound ^3H -dihydromorphine from particulate fractions of rat brain homogenates by naloxone. \circ , Control; \bullet , morphine-dependent animals.

Fig. 4 The displacement of bound ^3H -dihydromorphine from particulate fractions of rat brain homogenates by eserine. \circ , Control; \bullet , morphine-dependent animals.

same receptors as the narcotics themselves on the basis of *in vitro* binding studies⁸⁻¹⁰ and their very close structural similarity to the analgesics. Thus, if tolerance and dependence were simple the result of an increased number (or decreased affinity) of receptor sites much larger doses of antagonists should be required.

A body of evidence indicates that increased breakdown or neutralization of narcotics is also not responsible for tolerance. Thus, both brain and circulating levels of narcotic analgesics are generally similar or identical in normal and tolerant animals after administration of the same dose of a narcotic analgesic^{16,17}.

Apparently, narcotic drugs reach the brain and are bound at receptor sites to the same extent in both normal and tolerant animals. Tolerance and dependency therefore reflect a change in some subsequent process. Conceivably, the efficacy with which receptor binding is translated into the primary physiological response is greatly reduced in tolerant animals. Alternatively, physiological pathways which function in opposition

to the morphine-induced response may be greatly enhanced. This homeostatic mechanism is attractive in that it can easily predict the presence of strong withdrawal syndromes.

We thank Dr Irwin Kopin for morphine pellets and Drs Everette May and Howard Nash for advice and encouragement.

Toxic action of a phalloidin-albumin conjugate on cells with a high protein uptake

PHALLOIDIN (PHD) is a toxic cyclopeptide in *Amanita phalloides*^{1,2}. Rats and mice injected with this toxin die in 2-4 h from hepatic necrosis. Dilatation of the endoplasmic reticulum (ER) with the appearance of very large vacuoles are the first ultrastructural changes in hepatocytes^{3,4}. The first biochemical lesion produced by PHD is unknown². Hepatocytes are the only cells damaged by PHD in mice and rats^{5,6}; Heart fibroblasts⁷ and bovine kidney cells⁵ cultured *in vitro* are not affected by this toxin.

Two possible explanations why PHD damages hepatocytes and not other cells are: (1) PHD enters only hepatocytes; (2) only within these cells does it find the target for its toxic action.

In previous experiments (ref. 8 and E. Bonetti, M. D. and L. F., unpublished) it was found that amanitin-albumin conjugates produce the characteristic changes of amanitin poisoning in cells which are not damaged by the free toxin^{8,9}, but which are very active in protein uptake such as the sinusoidal liver cells of mouse¹⁰ and the kidney proximal tubule cells of rat^{11,12}. This finding demonstrated that these cells are susceptible to amanitin but that the toxin is unable to penetrate them unless it is coupled to a protein and so forced to enter by pinocytosis.

We have conjugated PHD to bovine serum albumin (BSA) and studied the effects of the conjugate (PHD-BSA) on macrophages cultured *in vitro* and also on liver sinusoidal cells and kidney proximal tubule cells of mice. The con-

jugation of PHD with BSA was performed as described for the coupling of amanitin to BSA⁸. The molar ratio of phalloidin to albumin in PHD-BSA was calculated according to Wieland and Buku¹³ and was found to be 2.3.

The effects of PHD and of PHD-BSA on mouse peritoneal macrophages are reported in Table 1. It shows that conjugation with BSA produces a very strong increase in toxicity of PHD for these cells.

TABLE 1 Effect of PHD and PHD-BSA on mouse peritoneal macrophages.

$\mu\text{g ml}^{-1}$ *	PHD		$\mu\text{g ml}^{-1}$ *	PHD-BSA	
	% dead cells			% dead cells	
100	25		400 (12) [†]	100	
50	10		200 (6)	100	
25	0		100 (3)	75	
12.5	0		50 (1.5)	75	

Mouse peritoneal macrophages, obtained as previously described¹⁴, were incubated at 37°C in 0.5 ml of Eagle's basal medium (BME) containing PHD or PHD-BSA. After 15 h 2 ml of BME with 10% foetal bovine serum were added and after further 9 h of incubation the number of dead cells was determined by staining with Trypan blue¹⁵. In the PHD-BSA experiment most of the cells were detached from the glass at the end of the incubation period.

* Concentration during the first 15 h of incubation.

[†] In parentheses the amount of PHD contained in PHD-BSA.

FIG. 1 Mouse killed 8 h after injection of PHD-BSA. Very large vacuoles (Vac) surrounded by a single membrane occupy large part of the cytoplasm of a liver sinusoidal cell. The cytoplasm of hepatocytes (Hep) looks normal. Fixation: 1% osmium tetroxide dissolved in 0.1 M Sorensen buffer, pH 7.2. Embedding: Araldite-Epon mixture according to Mollenhauer¹⁶. Staining: lead citrate. $\times 11,000$.

To study the effects of PHD-BSA on liver sinusoidal cells and kidney proximal tubule cells, Swiss male mice were killed 8 or 24 h after intraperitoneal injection of PHD-BSA dissolved in 0.9% NaCl at a concentration of 800 $\mu\text{g ml}^{-1}$ and given at the non-lethal dose of 80 μg per 10 g body weight ($=2.3 \mu\text{g PHD}$). Specimens of liver and kidneys were observed through the electron microscope.

Eight hours after injection of PHD-BSA, liver sinusoidal cells seemed damaged; the cisternae of rough ER were dilated, forming vesicles of different sizes. In some cells huge vacuoles surrounded by a single membrane occupied a large part of the cytoplasm (Fig. 1). They contained a fibrillar substance of low density, which was scattered in finely divided form. Many sinusoidal cells seemed detached from underlying hepatocytes whose microvilli jutted out directly into the sinusoidal lumen. No morphological alterations were found in nuclei. The hepatocytes seemed unchanged. Twenty-four hours after injection of PHD-BSA liver sinusoidal cells looked normal; they bordered the sinusoidal lumen everywhere.

In kidney PHD-BSA caused changes in the cells of the proximal convoluted tubules. The cells of every other portion of the renal tubular system were unaffected. This agrees with the finding that after injection of albumin in the mouse the only cells of renal tubular system which take up the protein are those of the proximal convoluted tubules¹¹. In these cells a marked increase in smooth ER was observed 8 h after PHD-BSA injection. After 24 h in many cells of the proximal convoluted tubules the cisternae of rough

FIG. 2 Mouse killed 24 h after injection of PHD-BSA. Cytoplasm of a proximal tubule cell of kidney. The cisternae of rough ER form vesicles of different sizes. LK indicates *Lipidkörperchen* (see text). Fixation, embedding and staining as in Fig. 1. $\times 45,500$.

ER were dilated, forming vesicles of different sizes (Fig. 2). This lesion is very similar to that observed in hepatocytes 15–30 min after PHD administration^{3,4}. Bodies surrounded by a single membrane, about 0.2 μm in diameter containing moderately dense, homogeneous material, which are a frequent finding in hepatocytes of mouse poisoned with PHD (*Lipidkörperchen*)⁵ were always observed in cells with dilated rough ER (Fig. 2). Some cells instead of the vacuolisation of rough ER showed the increase of smooth ER which is a common finding 8 h after PHD-BSA administration.

Our results show that conjugation with BSA makes PHD toxic for cells with a high protein uptake. The lesions produced by PHD-BSA are very similar to those caused in hepatocytes by free PHD^{3,4}. Since proteins after penetration into cells are rapidly broken down by lysosomal enzymes¹⁷, it seems likely that PHD-BSA exerts its toxic action within the cells after digestion of the protein moiety and release of free PHD from the conjugate. These results indicate also that the absence of lesions in cells different from hepatocytes following PHD administration is due to the inability of these cells to take up the toxin. Therefore the finding that the cells of gastrointestinal mucosa of mice are unaffected after injection of large doses of PHD (20 mg kg⁻¹ i.p.) (our unpublished observations) suggests that the toxin cannot enter these cells and explains why mice are very resistant to the toxin when it is given orally².

These results as well as previous data on amanitin-albumin conjugates (ref. 8 and E. Bonetti, M. D., and L. F., submitted for publication) suggest a possible use of conjugates in biological research. Substances such as hormones and drugs have biological activity only in some cells and sometimes it is difficult to assess whether they enter only the cells in which they are active or whether only within these cells do they find the target of their action. For some of these substances this problem might be solved by conjugating them to a protein and by testing whether in cells with a high protein uptake, the conjugates produce the same effects as are caused by free substances in target cells.

We thank Professor T. Wieland for a gift of phalloidin. The technical assistance of Mr L. Franchi and Mr A. Mattioli is acknowledged. This investigation was supported by grants from the Consiglio Nazionale delle Ricerche, Rome.

Sulphur-methylene isosterism in the development of metiamide, a new histamine H₂-receptor antagonist

BURIMAMIDE has been shown to antagonise the effects of histamine on isolated cardiac and uterine muscle *in vitro*, and to antagonise histamine-stimulated acid secretion *in vivo* in animals and in man¹. This pattern of pharmacological effects is not achieved by conventional, tertiary amine, anti-histaminic drugs (of which mepyramine is typical) and has led to the definition of burimamide as an H₂-receptor antagonist¹ and mepyramine as an H₁-receptor antagonist². Although burimamide was pharmacologically sufficiently active to allow for definition of its properties in man³ it seemed to lack the combination of high specific activity with adequate oral bioavailability needed for exploring the therapeutic potential of this new type of drug action. Attempts to produce a more suitable drug were based on the observation that burimamide is a competitive antagonist to histamine and that both compounds possess imidazole rings. We therefore compared the relative species populations of the respective rings and modified the burimamide structure so as to increase the equilibrium concentration of imidazole species considered most likely to be active.

In aqueous solution at physiological pH (7.4) burimamide exists as an equilibrium mixture of mainly three different imidazole species: the two uncharged tautomers A and B, and the cation C (Fig. 1, R = -(CH₂)₄NHCSNHCH₃).

FIG. 1 Three species of imidazole with a side chain R at position 4(5).

Moreover this equilibrium probably involves a water-mediated proton transfer which is not instantaneous, for example protonation of imidazole at pH 7 has a pseudo-first-order rate constant of $1.5 \times 10^3 \text{ s}^{-1}$ (ref. 4). If only one of these forms were active its relative population could determine the amount of drug required for a given effect. The populations of these species are determined by the relative acidities (pK_a) of the two ionisable protons in the cation, but these are not directly measurable. They can be estimated, however, from the electronic influence of the side chain. The substituent R alters the electron densities at the ring nitrogen atoms and affects proton acidity⁵. Its effect is more marked at the nearer nitrogen atom so that if R is an electron releasing group, tautomer B should predominate; if it is an electron withdrawing group, A should predominate. The fraction present as cation C is determined by the ring pK_a and the pH of the solution⁶. The electronic influence of the side chain can be assessed from the measured ring pK_a using the Hammett equation⁷: $pK_{aR} = pK_{aH} + \rho\sigma_m$, that is, the pK_a of the ring substituted by R is reduced relative to imidazole (R = H) in direct proportion to the electron with-

TABLE 1 Apparent pK_a values of substituted imidazole cations at 37° C and their mol fractions (n_c) at pH 7.4

					
	R ₁	R ₂	pK_a	Preferred tautomer	n_c at pH 7.4
Histamine	H	$-\text{CH}_2\text{CH}_2\text{NH}_3^+$	5.90	A	0.03
Thiaborimamide	H	$-\text{CH}_2\text{SCH}_2\text{CH}_2\text{NHCSNHCH}_3$	6.25	A	0.07
Metiamide	CH_3	$-\text{CH}_2\text{SCH}_2\text{CH}_2\text{NHCSNHCH}_3$	6.80	A	0.20
Imidazole	H	$-\text{H}$	6.80		0.20
Burimamide	H	$-(\text{CH}_2)_4\text{NHCSNHCH}_3$	7.25	B	0.40
4(5)-Methylimidazole	H	$-\text{CH}_3$	7.40	B	0.50
Methylburimamide	CH_3	$-(\text{CH}_2)_4\text{NHCSNHCH}_3$	7.80		0.72

pK_a determined potentiometrically at 25° C on 0.005M solutions in 0.1 MKCl by titration against HCl, corrected to 37° C by subtracting 0.0225 units per ° rise for values in the range 7.5 to 7.0 (ref. 11), and 0.02 for the range 6.5 to 6.0 (ref. 12) and rounded off to the nearest 0.05 unit.

drawing effect (σ_m) of R (the reaction constant, ρ , being negative). The pK_a values of relevant compounds are in Table 1.

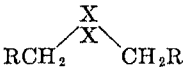

For histamine the ammonium-ethyl side chain ($R = -\text{CH}_2\text{CH}_2\text{NH}_3^+$) lowers the pK_a of the imidazole ring: it withdraws electrons and favours tautomer A. There is only a small proportion of cation C present at pH 7.4 (mol fraction $n_c = 0.03$); the main species is tautomer A, to the extent that approximately 80% of histamine molecules ($n_a = 0.80$) are in this form⁸. For burimamide the ring pK_a is greater than for imidazole, therefore the side chain ($R = -(\text{CH}_2)_4\text{NHCSNHCH}_3$) is electron releasing and tautomer B should be favoured. Electronically the side chain must resemble a methyl group since the pK_a is close to that of 4(5)-methylimidazole. At pH 7.4 the cation is one of the main species ($n_c = 0.40$) and tautomer A should be the least favoured.

Thus, although both histamine and burimamide are mono-substituted imidazoles, the structural similarity is misleading in that the predominant species of the respective imidazole rings are chemically different. If the active form of the antagonist were species A, the form most preferred for histamine, then activity might be enhanced by increasing its relative population. This could be done by converting the antagonist side chain into an electron withdrawing group, for example, by incorporating an additional electronegative atom in the side chain, preferably near to the ring. The disturbance to other molecular properties, such as stereochemistry and lipid-water partition, should however be kept minimal. One way would be to replace a methylene group ($-\text{CH}_2-$) by a thioether linkage ($-\text{S}-$). The data in Table 2 show that these are almost isosteric; they have similar van der Waals radii and give rise to similar bond

angles. The C-S bond is somewhat longer than a C-C bond so that in the thioether the adjacent methylene groups would be farther apart by 0.3 to 0.4 Å; this is quite a modest effect, amounting to an increase in distance between these two groups of about 15%. The thioether linkage may slightly increase conformational flexibility since the energy barrier to rotation of the C-S bond in the thioether linkage is lower than that of the C-C bond in the corresponding hydrocarbon. A sulphur atom is probably more hydrophilic than a methylene group; the octanol-water partition coefficient of diethyl sulphide ($\log P = 1.95$) suggests that the sulphur atom makes no additional contribution to the partition. Comparison with pentane ($\log P = 2.50$) shows that in this simple case replacement of CH_2 by S reduces partition by 0.5 log units, which amount is equivalent to the removal of a methyl or methylene group.

Making this substitution in burimamide at the carbon atom next but one to the ring gave the compound 'thiaborimamide' ($R = -\text{CH}_2\text{SCH}_2\text{CH}_2\text{NHCSNHCH}_3$). The effect on partition of the uncharged molecule is small. $\log P$ (at 37° C between 1-octanol and aqueous buffer at pH 9.0) is reduced from 0.39 (burimamide) to 0.16 (thiaborimamide). The electronic influence of the modified side chain, shown by the ring pK_a , is similar in magnitude but in the opposite direction to that of a methyl group. The main species should be tautomer A although its population may not be as large as it is in histamine because the electronic effect of the side chain is not as marked. A further increase in the population of tautomer A should be obtained by introducing an electron releasing substituent such as methyl in the vacant 4(5)-position of the ring, since electron releasing groups favour the form with the hydrogen atom on the adjacent nitrogen. The methyl group should not interfere with receptor interaction since it has been shown that 4-methylhistamine is an effective H_2 -receptor agonist¹. It might, however, exert an influence on the stereochemistry of the molecule by restricting rotation of the ring in a way analogous to that suggested to occur with 4-methylhistamine⁹. Incorporating methyl into the ring of the antagonist gave N-methyl-N'-[2[(5-methylimidazol-4-yl)methylthio]ethyl]thiourea, which has the name metiamide (name approved by the British Pharmacopoeia Commission and the US Adopted Names Council). The two ring substituents in metiamide are seen to have electronic effects of equal magnitude but of opposite direction. They should combine to favour tautomer A but oppose in their effect on ring pK_a ; indeed, they must exactly cancel since the pK_a s of metiamide and imidazole are identical. This means that at pH 7.4 the main species should be tautomer A, as for histamine, although there would still be a substantial proportion of cation present ($n_c = 0.20$). In comparison with burima-

TABLE 3 H₂-Receptor antagonist activities. The dissociation constant (K_B) was calculated from the equation $K_B = B/(x - 1)$, where x is the respective ratio of concentrations of histamine needed to produce half-maximal responses in the presence and absence of different concentrations (B) of antagonist, and $-\log K_B = pA_2$.

	Atrium K_B (95% limits) $\times 10^{-6}$ M	Uterus K_B (95% limits) $\times 10^{-6}$ M
Metiamide	0.92 (0.74 - 1.15)	0.75 (0.40 - 1.36)
Thiaborimamide	3.2 (2.5 - 4.5)	3.2 (2.5 - 4.5)
Burimamide	7.8 (6.4 - 9.6)	6.6 (4.9 - 8.3)
Methylburimamide	8.9 (5.6 - 15)	10.7 (4.5 - 31)

mid, the ratio of tautomers is reversed for metiamide and the proportion of cation is decreased.

The pharmacological consequences of these manipulations are shown in Table 3. The effectiveness of each compound as an H₂-receptor histamine antagonist was compared by estimating the dissociation constant, K_B , (with 95% confidence limits) for the drug-receptor complex. The reliability of these estimates was tested by making separate measurements on two tissues, heart muscle and uterine muscle, which came from different animal species and which respond to histamine in different ways; heart muscle is stimulated and uterine muscle is inhibited. Further, the antagonism was shown to be specific by the failure to antagonise isoprenaline which apparently has identical pharmacological effects to histamine in these tissue¹. The results obtained on the two tissues are in good agreement and, taken together, show that metiamide *in vitro* is three to four times more active than thiaborimamide and eight to nine times more active than burimamide.

Thus it can be seen that modifying the side chain in burimamide by isosteric replacement of $-\text{CH}_2-$ by $-\text{S}-$ favours tautomer A, reduces the ring pK_a , and gives a more active compound (thiaborimamide). Introducing a 4(5)-methyl group to give metiamide increases further the preference for tautomer A but decreases the combined populations of the uncharged tautomers (A and B) through raising the ring pK_a . But although these are opposing effects the net result is that metiamide is more active still. By contrast, the analogous structural modification of burimamide, incorporation of a ring 4(5)-methyl group to give 'methylburimamide' does not increase activity. In this case the two ring substituents have nearly equal electronic effects in the same direction; the methyl group counterbalances the electronic influence of the side chain on tautomerism so that the two tautomers become equally populated, but it raises the ring pK_a to 7.80 so that at pH 7.4 the predominant species is the cation C ($n_c = 0.72$). This illustrates the problem of attempting to manipulate the biological properties of drug molecules through altering the structure. The changes in chemical properties accompanying structural modification often impose their own inherent limitations; a structural change, biologically advantageous with respect to a given chemical property, may affect some other chemical property in a biologically disadvantageous way and one has to discover the optimum balance of opposing influences. Finally, metiamide is not only a more active H₂-receptor antagonist than is burimamide *in vitro*, it is also more active *in vivo*. Metiamide has sufficient oral activity in animals and man as an inhibitor of evoked gastric acid secretion for consideration in therapy¹⁰.

Similarity in the Sequence of *Escherichia coli* Dihydrofolate Reductase with Other Pyridine Nucleotide-requiring Enzymes

DIHYDROFOLATE reductase (DHFR) is a NADPH-requiring enzyme, and as isolated from a methotrexate-resistant strain of *E. coli* B^{1,2}, has two binding sites for NADPH³. The sequence of DHFR (Fig. 1) has been determined recently in our laboratory by standard methods including CNBr cleavage, enzymatic digestion, and manual Edman degradation with direct determination of the phenylthiohydantoin by gas chromatography and thin-layer chromatography. Novel methods used included free flow electrophoresis instead of ion exchange chromatography for the separation of peptides from tryptic digestion, and cellulose acetate electrophoresis to monitor separations of the peptides produced by CNBr. Details of this work will be reported elsewhere (C. D. B., J. A. Rodkey and J. M. Sondey, manuscript in preparation).

Engel⁴ has pointed out the similarities between the sequence of amino acids around the lysine active in cofactor-binding of glutamate dehydrogenase (GDH) with a second sequence in GDH, which he suggested might be the site of 'regulator'

In normally innervated adult muscle, membrane sensitivity to acetylcholine (ACh) is localised to the endplate and tendon regions^{1,2}. After surgical denervation, this sensitivity spreads over the entire membrane surface reaching a peak within 5 to 7 d (ref. 3). Two hypotheses have been proposed to explain the restriction of ACh sensitivity in normally innervated muscle. The first suggests that a trophic substance is released from the motoneurone, restricting transmitter sensitivity to the endplate region^{4,5}. The second hypothesis suggests that muscle 'activity' generates a self-feedback loop from the muscle onto the sarcolemma thus limiting ACh sensitivity to the neuromuscular junction^{3,6}. Upon denervation, muscle 'activity' ceases and therefore the feedback loop is broken with the consequent loss of activity-mediated transmitter sensitivity restriction. Drachman and Witzke⁷ showed that direct electrical

stimulation of the denervated rat diaphragm, resulting in contraction, suppressed the spread of ACh supersensitivity. Jones and Vrbová⁶ reported that chronic electrical stimulation of the extensor digitorum of rat, resulting in contractions, reduced supersensitivity to ACh subsequent to denervation.

If muscle 'activity' is responsible for limiting ACh sensitivity to the endplate region, then feedback information from the muscle could emanate either from the contractile event or from membrane events in the absence of excitation-contraction coupling. To determine if mechanical activity, *per se*, is a necessary condition for limiting ACh sensitivity, or whether fluctuations in membrane potential alone constitute a sufficient signal for transmitter sensitivity restriction, we have stimulated denervated muscle above and below the mechanical threshold.

Both extensor digitorum longus (EDL) muscles from albino rats weighing 300 to 400 g were denervated by removal of a 1 to 2 cm section of the deep peroneal nerve between the EDL and the knee⁵. Teflon coated, multistrand wire (32 gauge) was wrapped once around the tendon of origin and insertion and secured by a nylon ligature to nearby connective tissue. The wire was fed through a small diameter polyethylene tube, previously introduced subcutaneously from the thigh to the neck, where it was brought to the surface for connection to a stimulator. One EDL of the first group of animals was electrically stimulated with 5 ms pulses, at a frequency of 15 pulses s⁻¹ and an amplitude of 6.6 ± 0.1 V for 1 h d⁻¹ over a period of 4 d commencing 24 h after denervation. Stimulus intensity was adjusted to a level resulting in maximal contractions as observed with a surgical microscope at $\times 80$ magnification. The other

1×10^{-5} M ACh. After a washout period of 5 min in RR, the muscles were challenged with a solution containing 1×10^{-3} M ACh. Isometric tension was measured with two RCA 5734 mechano-electric transducers and recorded on a Hewlett-Packard paper recorder. Tension measurements were standardised by calculating tension per unit wet muscle weight. The results from paired muscles are shown in Table 1. The data show that sensitivity to ACh from subliminally stimulated muscles is consistently decreased by up to 38% when compared to sham stimulated muscles. The data also indicate that there is no difference between subliminally stimulated and maximally activated muscles.

On this basis we conclude that the feedback information from the muscle onto its sarcolemma is not necessarily mediated by activation of the contractile machinery itself. Muscle membrane potential fluctuations, induced by subliminal electrical stimulation, are therefore sufficient to restrict the spread of denervation-induced transmitter supersensitivity. The reduction of supersensitivity by subliminal stimulation must represent a minimum value as it is quite likely that centrally located fibres did not receive sufficient current to be affected. Therefore, if we were to eliminate the contribution to ACh sensitivity of these centrally located fibres, the reduction in sensitivity would be even greater than we report here. This consideration, no doubt, also contributes to the rather large variability in the response of different muscles owing primarily to the different current densities which depend on muscle geometry. Our results confirm earlier reports^{3,7} that electrical stimulation of denervated muscle is effective in limiting the spread of denervation-

* Acetylcholine was dissolved in rat Ringer solution having the following composition: 160 mM Na⁺, 5 mM K⁺, 2 mM Ca²⁺, 1 mM Mg²⁺, 146 mM Cl⁻, 15 mM HCO₃⁻, 5 mM Tris buffer, 5 mM HPO₄²⁻, and 11 mM glucose at pH 7.1, saturated with 95%–5% O₂–CO₂.

† All muscles were denervated and connected to the stimulator wires in an identical manner. No stimulating current was delivered to the sham muscles. Stimulated muscles received trains of rectangular pulses lasting 5 s. Pulses within the trains had a duration of 5 ms and a frequency of 15 s⁻¹. The amplitude of the pulses delivered to the subliminal muscles was adjusted to a level just below any visually detectable mechanical activity, whereas maximal muscles received stimuli whose amplitude resulted in maximal mechanical activation. *n*=number of muscle pairs.

‡ Values given are means \pm S.E.M. in g tension per g wet muscle weight.

§ Significant at the 0.05 level.

EDL of each animal was stimulated in the same manner except that stimulus intensity was adjusted to just below the mechanical threshold (3.9 ± 0.1 V) as judged from frequent microscopic observations of superficial fibres.

One muscle from a second group of animals was stimulated for 48 h continuously with trains of square pulses lasting 5 s. Pulses within the train had a duration of 5 ms, a frequency of 15 s⁻¹ and a pulse amplitude of 2.9 ± 0.3 V. This amplitude was just below the mechanical threshold (subliminal stimulation). The inter-train interval was 7 s. The other muscle of each animal served as a control. It was denervated and connected to the stimulating wire as described above except that no current was passed to that muscle (sham stimulation). Two hours after the end of the stimulation regime, both muscles from the same animal were excised and mounted in a constant temperature chamber at $37 \pm 1^\circ$ C. The muscles were continuously superfused with rat Ringer (RR) solution saturated with 95% O₂, and 5% CO₂ at a flow rate of 40 ml min⁻¹ (Table 1). The muscles were stretched to a resting tension of 5 g and equilibrated in RR for 5 min before being challenged with RR solution containing

induced supersensitivity. In addition, our data favour the hypothesis that sarcolemmal sensitivity to ACh is regulated by a mechanism located in or near the muscle membrane. This mechanism could be activated by fluctuations in membrane potential without the necessary involvement of excitation-contraction coupling.

Role of Muscle Activity in Nerve-Muscle Interaction *in vitro*

CLONAL nerve and muscle cells interact *in vitro* to produce a nerve-muscle contact which is associated with an area of increased acetylcholine sensitivity on the muscle^{1,2}. This association is reminiscent of the distribution of acetylcholine sensitivity on innervated skeletal muscle *in vivo*^{3,4}. It is possible to use cultures of nerve and muscle cells to examine the requirements for localisation *in vitro*. A previous report showed that cholinergic transmission is not required². Here I discuss the requirement for muscle electrical and contractile activity in localisation of acetylcholine sensitivity.

To examine the requirement for muscle activity in the events leading to localisation, it was necessary to block the electrical and contractile activity in muscle fibres. The action potential is resistant to 3×10^{-7} M tetrodotoxin⁵ and 5 mM procaine was toxic on prolonged exposure. However, both the action potential and delayed rectification are inactivated by prolonged depolarisation (Y. Kidokoro, in preparation), as is the case in frog skeletal muscle fibres⁶. The resting membrane potential is largely determined by a K^+ permeability, so it is possible to depolarise the cells by increasing the external K^+ concentration. When the external K^+ was increased from 5.3 to 25.3 mM by adding sterile 1 M KCl to growth medium⁷, the membrane potential was depolarised to about -40 mV and remained depolarised up to 2 weeks (-39 ± 5 mV, $N=48$). The resting potential in 5.3 mM K^+ is about -70 mV.

Muscle fibres remained depolarised throughout a long term exposure to 25.3 mM K^+ medium, but it was necessary to show that action potentials were still blocked. Accordingly, muscle fibres grown in medium with 25.3 mM K^+ (high K^+) for 10–14 d, were penetrated with two microelectrodes while still in high K^+ . To elicit even a partial action potential, a fibre had to be polarised to at least -70 mV for 100 or more ms

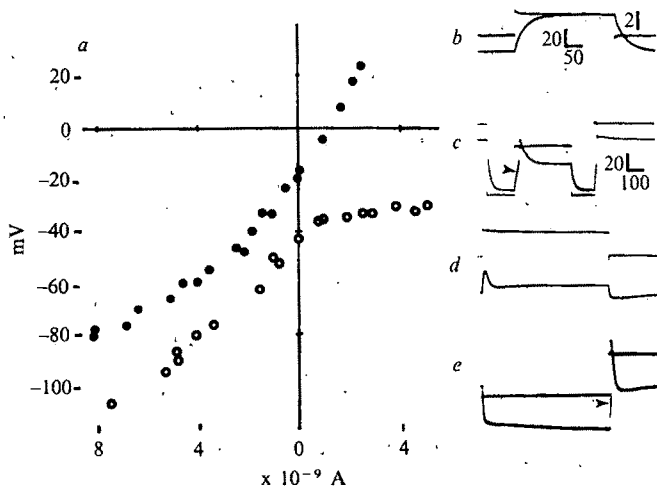

Fig. 1 The steady-state current-voltage relationship (measured 200 ms after the start of the current pulse) for a muscle exposed to high K^+ medium for 12 d and studied in high K^+ , is shown in (a) (solid circles); that for a muscle fibre fused in high K^+ , grown for 14 d, then studied in normal K^+ is shown by hollow circles. Samples traces from the same fibres are shown. (b) Shows the absence of delayed rectification in high K^+ , while (d) shows its presence in the fibre formed and grown in high K^+ . (c) Shows that only a partial action potential can be evoked from this fibre in high K^+ (a hint of the potential can be seen at the end of the hyperpolarizing pulse, but it is more clearly shown by the superimposed depolarization). (e) Shows an overshooting action potential in the fibre fused in high K^+ , then studied in normal K^+ . Note that the inflections in the rising phase of the action potentials occur at -50 to -60 mV (arrows). Calibrations are shown in the figure—the upper trace shows injected current ($\times 10^{-9}$ A) and zero membrane potential, the lower shows membrane potential (mV), time is in ms. The calibrations are the same for (c), (d) and (e).

(Fig. 1c). The steady state current-voltage relationship in high K^+ showed anomalous rectification; rather than delayed rectification (Fig. 1a). No permanent changes had been made in membrane properties, however, since when fibres exposed to high K^+ for 2 weeks were washed and studied in normal K^+ medium, they immediately (that is, the first cell penetrated) could generate overshooting action potentials on anode break stimulation, and showed delayed rectification. Furthermore, myoblasts grew and fused normally in high K^+ . Action potentials and delayed rectification were inactivated in high K^+ in these fibres, as just described for fused fibres chronically exposed to high K^+ . Again, if such fibres (fused in high K^+) were washed and studied in normal K^+ , they also could generate overshooting action potentials (Fig. 1e) and showed delayed rectification (Fig. 1a and d).

Table 1 Average Enhancement of Sensitivity at Nerve-Muscle Contacts

No. of muscle fibres	Ratio of peak localised sensitivity to background (Average)	sensitivity (Range)	No. of sites tested per cell (Average)	(Range)	Success, 0.7
11	18	6–44	23	8–63	0.7

L6 myoblasts⁸ and N18 neuroblastoma cells⁹ were cultured as described previously². The distribution of acetylcholine sensitivity was determined by penetrating a muscle fibre with a 3 M KCl-filled micropipette (70–150 M Ω), then applying acetylcholine iontophoretically from an extracellular pipette filled with 2.7 M acetylcholine chloride (100–300 M Ω)². The acetylcholine sensitivity of the membrane is defined² as the membrane depolarisation (in mV) divided by the amount of charge (in nC) passed through the acetylcholine pipette to produce the response (mV nC⁻¹). The results are pooled for fibres which had the 25.3 mM K^+ medium added before or after myoblast fusion, since localisation occurred in either case. The number of sites tested per cell gives the number of different areas of membrane that were tested with applied acetylcholine. 'Success' is the ratio of the number of muscle fibres that showed localisation to the number of nerve-muscle pairs that were chosen for study on the basis of their appearance in the phase microscope. The site of contact had to be clearly visible and situated so that the acetylcholine sensitivity could be determined all around it, and it had to be possible to trace the nerve process back to a nerve cell body.)

High K^+ medium reversibly stopped the twitching of spontaneously active muscle fibres. Fibres in high K^+ did not contract in response to intracellular stimulation or iontophoretically applied acetylcholine. These observations are consistent with studies on frog muscle fibres, which first contract when exposed to an increased K^+ concentration, then relax and no longer respond to electrical stimulation¹⁰.

To determine whether muscle activity was required in the events leading to localisation of acetylcholine sensitivity *in vitro*, nerve and muscle cells were cultured together in high K^+ medium for 8–12 d. In some studies the high K^+ was added to cultures of myoblasts before they had fused. In all studies high K^+ medium was added before the nerve cells and all electrophysiology was done in high K^+ medium, so that the block of activity was in effect throughout the experiment. Many examples of localisation of acetylcholine sensitivity were found, as seen in Fig. 2 and Table 1. In each case the peak of sensitivity was found at a nerve-muscle contact, and there was a clear gradient of sensitivity across the muscle surface up to the peak (see ref. 2 for further discussion).

I concluded from these results that muscle action potentials and contractile activity are not required for the events leading to the association of a nerve-muscle contact with an area of increased acetylcholine sensitivity on the surface of the muscle in this clonal system. Muscle fibres in primary cultures of chick embryo tissue can generate areas of increased acetylcholine sensitivity¹¹, or receptor density¹² in the absence of nerve cells. It is not known whether the localised sensitivity seen at a point of nerve-muscle contact in clonal cell culture preceded the contact or was induced by the intercellular contact.

The results obtained when high K^+ medium was added to myoblasts before fusion show that, in either case, muscle activity was not required for its production.

Recent studies have shown that electrical stimulation of denervated muscle *in vivo*^{13,14} can reduce the extrajunctional sensitivity, and stimulated muscle fibres *in vitro* are less sensitive than tetrodotoxin-treated fibres¹⁵. These studies strongly suggest that muscle activity influences the extrajunctional sensitivity on muscle fibres. However, results which are difficult to reconcile with the conclusion that muscle activity strictly determines the extrajunctional sensitivity have been reported¹⁶⁻¹⁸, and the relationship between muscle activity and sensitivity is not clear at present. Specifically, although activity reduced the extrajunctional sensitivity of denervated muscle, no effect on junctional sensitivity was noted¹³. It is possible that junctional and extrajunctional sensitivities are controlled by different processes and might be differently affected by muscle activity. It is not known whether the localisation seen in this clonal cell culture involves a decrease in the background sensitivity on the muscle cell (further discussion in ref. 2). Thus, there is no contradiction between the present results and other studies¹³⁻¹⁵.

My results demonstrate that muscle activity is not required for the localisation of acetylcholine sensitivity on these fibres *in vitro*, but do not indicate whether muscle activity has other effects on sensitivity (perhaps on the extrajunctional sensitivity, for example, refs 13-15).

Fig. 2 Examples of localization of acetylcholine sensitivity. The ordinate shows the acetylcholine sensitivity (in $mV nC^{-1}$) detected at various points on the muscle surface, while the abscissa shows the distance in μm between the indicated site and the site with the maximal sensitivity. In each case, the peak of sensitivity was at a nerve-muscle contact. In (a) and (b), the 25.3 mM K^+ solution had been added to cultures of fused muscle fibres; in (c) the 25.3 mM K^+ solution had been added to a culture of myoblasts before fusion.

Spine Loss and Regrowth in Hippocampus following Deafferentation

SEVERAL studies have reported that there is a loss of dendritic spines after partial deafferentation. It is known that terminals lost to a structure after injury to one of its afferents are replaced in part or whole by sprouting of undamaged inputs¹⁻³. This raises questions as to the nature of the accompanying post-synaptic changes but no attempts have been made to follow the loss of spines over time⁴⁻⁶. Specifically, there are no data on whether spines are replaced when sprouting afferents invade deafferented dendritic zones. This is a critical question if the nature of the morphological reorganisation which follows lesions in the brain is to be understood.

We therefore studied the effects of lesions of the entorhinal cortex on the spine population of neurones in the dentate gyrus. The entorhinal cortex generates the temporo-ammonic tract⁷⁻¹⁰, which contributes more than half of the synapses in the outer molecular layer of the dentate gyrus (D. A. Matthews, C. W. C., and G. L., unpublished). Following its removal, axons of the commissural system (which occupies the inner molecular layer) and the crossed temporo-ammonic tract (which terminates on the apical dendrites of CA1 pyramids) invade the outer molecular layer and form functional terminals¹¹⁻¹⁴. The scattered AChE terminals, probably originating in the septum and located in the outer molecular layer, proliferate after entorhinal lesions¹⁵⁻¹⁶. Thus, considerable replacement of the temporo-ammonic tract terminals occurs in the outer molecular layer after entorhinal lesions. Here we report changes which occur on dendritic spines of cells in the molecular layer while this axonal growth takes place.

Large electrolytic lesions were placed in the entorhinal cortex of adult rats of both sexes. The animals (E) were sacrificed at 5 ($n=4$), 20 ($n=4$), 60 ($n=4$) and 100 ($n=4$) d. An equal number of animals of the same age and approximately of the same weight served as controls (C). The rats were anaesthetised with ether. Tissue was excised from the rostral hippocampus and immediately immersed in rapid Golgi fixative of osmium tetroxide and potassium dichromate for 6 d. After fixation, the blocks were placed in 0.75% silver nitrate for 24 h. They were then 'shelled' in paraffin and cut on a sliding microtome at 75 μm . Following two washes each with absolute ethanol, methyl salicylate and xylene, they were mounted under Per-

mount. The rapid Golgi method silhouettes the soma-dendritic complex in detail including the dendritic spines¹⁷.

Spines were counted in the outer and inner molecular layers of the dorsal leaf of the dentate gyrus ipsilateral to the entorhinal lesions. Counts were performed on 45 μ m segments (stations) on fifteen granule cells per animal (Fig. 1). All measurements in the outer molecular layer were taken from dendritic branches located within 100 μ m of the hippocampal fissure and those for the inner molecular layer were made within 100 μ m of the granule cell layer. As far as possible the same medial-lateral segment of dentate gyrus was examined in each rat.

Spine density was essentially the same in both layers in normal rats (Table 1). Five days after the entorhinal lesion there was a 30% reduction in the number of spines of the outer molecular layer (Fig. 2) but no changes were found in the inner molecular layer. By 20 d after the lesion, spine density had returned to 80% of normal and was back to control levels 60 d after the lesion (Table 1).

Table 1 No. of Dendritic Spines per μ m of Dendrite

Station	Controls (C)	Experimental (E)	% difference*	P†
5 d after lesion

† Student's *t* test.

‡ Standard deviation.

It is interesting to compare the time course reported above with that reported for the invasion of axonal sprouts into partially denervated dendritic territory. Raisman and Field reported that the terminal population of dendritic spines in the

Fig. 1 Counting stations along the dendrites of the hippocampal granule cell. Stations A and B are located in the inner and outer molecular layers of the dentate gyrus respectively.

Fig. 2 A, Density of spines in the outer molecular layer of a normal adult rat; B, loss of spines as a result of an electrolytic lesion in the entorhinal cortex 5 d after the operation. * Portions of dendrite in focus.

septal nuclei was reduced to one-half of normal values 7 d after section of their hippocampal projections but returned to normal values by 30 d after the lesion¹⁸. The new terminals are thought to arise in part from sprouting of medial forebrain bundle axons. Neurophysiological studies have shown that the crossed temporo-ammonic¹⁴ and commissural (J. West, S. Deadwyler, C. W. C., and G. L., unpublished) systems establish functional synapses in the outer molecular layer 10 to 14 d after a lesion to the entorhinal cortex. Finally, histochemical experiments indicate that the process of axon sprouting is begun 5 to 7 d after lesions¹⁹. Taken together, these findings indicate that axon sprouting starts within 7 d of a lesion, establishes some functional synaptic contacts by 14 d after the lesion, and is essentially completed within 30 d of the lesion.

Although our data do not provide a precise picture of the time course for spine regrowth it is evident that the process is occurring during the period in which axonal sprouting takes place. This leads to the suggestion that the two processes, namely spine regrowth and axonal sprouting, might be related. Spine formation during development is often hypothesized to be dependent upon the arrival and normal function of axon terminals. We suggest that a similar mechanism occurs in the adult. A reduction of afferents results in loss of spines. Replacement of afferents by sprouting generates a new spine population. A special case of this is data reported by Valverde²⁰ from a study in which he raised mice in complete darkness from birth to 20 d and then placed them under normal lighting conditions for periods of up to 30 d. He claims 'recovery' of some spines on apical dendrites in the visual cortex of these animals—and suggests that the development of this group of spines results from the arrival of normal visual inputs. The possibility exists that there may be little or no correspondence between the two studies.

Our hypothesis, stated above, might also explain why several workers have observed a permanent reduction in spine densities following lesions^{5,6}. There is evidence that post-lesion sprouting is not a universal effect^{21,22}. If some brain regions are not re-

innervated by sprouting after the removal of afferents, then spine loss should be permanent.

Finally, these experiments provide clues as to factors which regulate spine density. The dendritic zones deafferented by the entorhinal lesions are re-innervated by three and possibly more different axonal systems. If spine density were solely dependent on the growth potential of presynaptic elements it would hardly be expected that these diverse inputs would generate the same number of spines as the single afferent they replace. Yet our data indicate that spine densities return to values essentially identical to pre-lesion conditions. A more parsimonious hypothesis is that granule cells in the hippocampus are capable of producing a certain number of spines. Given that an adequate number of terminals is present, these cells will generate this quantity of spines independent of the specific type of afferents.

Growth Hormone Releasing Factor of Microbial Origin

CHOLERA enterotoxin mediates specific biochemical events in both intestinal and non-intestinal tissues by stimulating adenylyl cyclase and cyclic AMP^{1,2}. Other evidence points to a role for cyclic AMP in regulating the secretion of several hormones by their respective endocrine glands³. These findings have led us to investigate whether cholera enterotoxin affects the secretory function of pituitary cells.

Cholera enterotoxin, an extracellular protein of molecular weight 84,000, was purified from culture filtrates of *Vibrio cholerae*, Inaba 569B, as described earlier⁴, adding Sephadex-G-150 chromatography as a final step. Absence of residual somatic antigen was established by the failure of detoxified enterotoxin preparations to elevate vibriocidal antibody; and absence of choleraenoid, a degradation product of toxin⁵, was shown by acrylamide gel electrophoresis.

Monolayer cultures of enzymatically dispersed cells from whole pituitaries of Charles River CD male rats were prepared essentially according to Vale *et al.*⁶ and Grant *et al.*⁷. The growth medium was Eagle's minimal essential medium containing 10% foetal calf serum plus standard amounts of glutamine and antibiotics, and the test medium was Earle's balanced salt solution plus antibiotics. After incubation of cell monolayers with and without enterotoxin for 3 h at 37° C, replicate culture fluids were analysed for growth hormone, prolactin, luteinising hormone and thyrotropin by specific double antibody radioimmunoassay. Results were evaluated by analysis of variance, using Dunnett's procedure for multiple comparisons.

Treatment of cell monolayers with concentrations of enterotoxin from 6×10^{-8} M to 6×10^{-9} M significantly increased the basal secretions of all four hormones (Table 1). Enterotoxin concentrations from 6×10^{-10} M to 1.2×10^{-13} M, however, preferentially raised the secretion of growth hormone. In each

Fig. 1 Monolayer cultures of rat pituitary cells incubated for 3 h at 37° C with test medium (top) or test medium containing 1.2×10^{-11} M of cholera enterotoxin (bottom). Magnification $\times 320$, phase contrast, stained with May-Greewald and Giemsa.)

experiment, the growth hormone response was dose-related. Neither cholera toxoid⁸ at a concentration of 50 μ g ml⁻¹ nor enterotoxin preincubated with specific antitoxin could increase hormone secretion. In addition, cholera toxin, a competitive inhibitor of enterotoxin⁹, and somatostatin, the growth hormone release inhibitory factor¹⁰, each at a concentration of 2.2 $\times 10^{-8}$ M, depressed the release of growth hormone by 1.2 $\times 10^{-11}$ M enterotoxin.

After treatment with enterotoxin, cells remained viable on the basis both of their ability to exclude trypan blue dye and their ability to be subcultured. Further, enterotoxin treatment produced a striking change in morphology: the cells developed elongated cytoplasmic processes which became noticeable within 1 h of exposure to enterotoxin and which, in some cases, seemed to form webs of interconnecting cells (Fig. 1). Replacement of test medium with growth medium alone reversed the morphology to that of the control cultures. Reintroduction of test medium without enterotoxin, however, led to the same morphological transformation which occurred during treatment with enterotoxin, suggesting that the toxin had been irreversibly bound to the cell membrane. In contrast to enterotoxin-treated cultures, monolayers treated with luteinising hormone releasing hormone (LRH) did not exhibit the transformation.

To determine whether cyclic AMP mediated the secretion of growth hormone by the morphologically transformed cells, control cells and cells treated with 1.2 $\times 10^{-11}$ M enterotoxin were collected by trypsinisation and analysed for intracellular cyclic AMP by the method of Gilman¹¹. Enterotoxin-treated cells, secreting four times more growth hormone than control cells, contained approximately twice the intracellular cyclic AMP found in control cells. Cultures more homogeneous with respect to growth hormone-producing cells would probably have an even greater influence of enterotoxin on cyclic AMP content.

In considering the mechanism governing the preferred release of growth hormone at low concentrations of enterotoxin, we compared the kinetics of this release with the kinetics of a well-defined hypothalamic releasing hormone, LRH. The time course of enterotoxin-induced secretion of growth hormone resembled that of LRH-induced secretion of luteinising hormone: significant release of each hormone failed to appear

before 1 h, but for 2 h afterwards both secretions increased linearly with time. This similarity suggests that the sequence of events leading to secretion may be the same.

These findings provide the basis of a sensitive new assay for cholera enterotoxin. The changed morphology of the pituitary cells may in itself offer a rapid and simple means of detection. Moreover, since cholera enterotoxin comprises a large protein marker with specificity for growth hormone-secreting cells, it should facilitate isolation and characterisation of the particular receptors involved.

Taken with the evidence that cholera enterotoxin elevates steroid production in cultured mouse adrenal cells¹², our findings pose the question of whether the toxin may alter host hormone secretion during the course of the disease. Although systemic penetration by enterotoxin has not been demonstrated in clinical or experimental cholera², a peptide fragment of the molecule, small enough to pass through the intestinal mucosa, may retain the minimum structural requirements for stimulating pituitary receptors.

We thank the National Institute of Arthritis and Metabolic Diseases Rat Pituitary Hormone Distribution Program for radioimmunoassay reagents; anti-rat growth hormone was supplied by Dr R. E. Grindland of the Ames Research Center.

Note added in proof. We have found recently that enterotoxin from two strains of *E. coli* also stimulates growth with an accompanying morphological transformation.

Histochemical study of an inhibitor of fibrinolysis in the human arterial wall

THE formation of fibrin is a fundamental biological repair mechanism, but the fibrin has ultimately to be removed by fibrinolysis. This is accomplished by the proteolytic enzyme plasmin, which is converted from plasminogen, an inactive precursor in blood, by an activator. Astrup and Permin¹ have demonstrated that the fibrinolytic activity of tissues is due to such an activator of plasminogen.

To localise fibrinolytic activity in different tissues, Todd² developed a histochemical method in which frozen tissue sections are covered by a thin layer of fibrin rich in plasminogen. During incubation at 37° C, structures containing the plasminogen activator caused lysis which appeared as clear zones in the subsequently stained fibrin. By means of this fibrin slide technique, several investigators^{3,4} found the plasminogen activator in human tissues to be concentrated predominantly in endothelial cells of capillaries and veins.

The endothelial cells of the lumen of human arteries usually showed no activity, however, in contrast to the vasa vasorum of their adventitia. This remarkable lack of activity in endothelial cells of human arterial intima prompted us to carry out a renewed investigation of human muscular and elastic

FIG. 1 Lysis produced by the vasa vasorum in the adventitia of the hepatic artery. Left, an initially small zone of lysis; right, an extended zone with flattening towards the media. Harris' alum haematoxylin ($\times 50$).

arteries, as well as veins, by means of the fibrin slide technique. For discrimination between plasminogen activator activity and non-specific protease activity, we prepared slides with bovine fibrinogen with and without plasminogen⁵.

We confirmed the original finding that fibrinolytic activity due to an activator of plasminogen is related to endothelial cells of most veins and capillaries, but not to those of arterial intima. During this investigation, however, our attention was drawn to an outstanding recurrent phenomenon: the initially

FIG. 2 Cross sections of the splenic artery unheated (a) and heated (b) assayed on plasminogen-free fibrin with the fibrin slide sandwich technique using plasmin as active compounds. After incubation for 140 min, a dark-stained fibrin strand remains on top of the media of the unheated section, while on the heated section all fibrin is lysed. Harris' alum haematoxylin ($\times 5$).

small round areas of lysis due to plasminogen activator in the vasa vasorum of the arterial adventitia flatten towards the site of the media, while they extend during prolonged incubation. Consequently, their centres shift to lateral (Fig. 1). This feature was more pronounced in human muscular than in elastic arteries, while the distortion of lytic zones was hardly noticeable around large human veins. A possible explanation for this could be that medial tissue contains an inhibitor of fibrinolysis which may diffuse into the fibrin layer above it, thus preventing lysis at those sites.

Evidence for this hypothesis was given by demonstrating the inhibition of fibrinolytically active compounds placed on top of the medial site of human arteries. This was achieved by modifying the fibrin slide technique as follows: frozen sections of the tissue to be examined were placed on a microscope slide, covered by fibrin, and left for at least 2 h in a moist refrigerator, to allow diffusion of inhibiting components from the sections into the fibrin layer. Fibrinolytically active frozen sections were then placed on top of the fibrin film after which the preparations were incubated for various lengths of time at 37° C, fixed, and stained. We called this technique the 'fibrin slide sandwich technique'⁶. When used on fibrin films rich in plasminogen, the fibrinolytically active layer of the 'sandwich' consisted of a frozen section of human lung known to be rich in plasminogen activator, or a section of a frozen urokinase solution (human urokinase, Leo Pharmaceuticals, Copenhagen, dissolved to 7 Ploug units ml⁻¹ in saline barbitol buffer with 15% gelatin). Human plasmin⁷ (Michigan Department of Public Health, Michigan, diluted to 1.5 U ml⁻¹ in saline with 15% gelatin) was used on plasminogen-free fibrin.

By means of the sandwich technique using both activator and plasmin as the active layer, a clear inhibition of fibrinolysis was demonstrated in the medial area of fresh human arteries but not in the adventitial region. This inhibitory effect was indicated by a dark-stained fibrin strand remaining on top of the media while the active top layer had lysed most of the fibrin which it contacted. Usually some fibrin is observed remaining in the lumen at the moment when the fibrin adjacent to the adventitia is already lysed (Fig. 2a). Inhibition of both activator and plasmin by human elastic arteries was not as effective as by muscular ones; the walls of large veins, for example the superior vena cava, showed very little inhibition.

During further attempts to confirm our evidence, it was discovered that heating tissue sections in a dry oven at

100° C for 12 h before covering with fibrin abolished the inhibition effect. The absence of a dark-stained fibrin strand on top of the media of a heated section (Fig. 2b) shows the loss of inhibition in contrast to its presence in fresh sections (Fig. 2a).

Our results thus indicate the presence of an inhibitor of fibrinolysis in the human arterial wall which is able to diffuse into fibrin. This provides a natural explanation for the distortion of lytic zones to the medial site, and possibly for the absence of fibrinolytic activity in the arterial intima as seen with the fibrin slide technique. The physiological significance of this inhibitor in human arteries remains to be discovered, but its presence should be kept in mind when considering the role of fibrinolysis in vascular disease.

Temperature-sensitive Mammalian Cell Line Blocked in Mitosis

SEVERAL temperature-sensitive mammalian cell mutants in culture have been isolated¹⁻¹⁰, including three defective in protein syntheses⁶, cytokinesis⁵ and the processing of ribosomal RNA¹⁰, respectively. I have now isolated a hamster cell mutant in which mitosis is blocked in metaphase.

Hamster cells HM-1 from Kam Laboratories were grown in Dulbecco's modified Eagle's minimal essential medium (MEM) supplemented with 10% calf serum (Grand Island Biological

Fig. 1 Growth of ts-546 at 33° and 39° C. Falcon 60-mm culture dishes were inoculated with cells and incubated at 33° C for 3 d. Half the dishes were transferred to 39° C. The medium in two dishes was removed, trypsin added and cell number counted at the time of transfer (time 0) and at intervals thereafter. □, Cells at 33° C; ●, at 39° C.

Fig. 2 Incorporation of labelled precursors by ts-546 cells. All the steps were carried out in warm rooms with temperature fluctuation controlled within $\pm 0.05^\circ$ C. 1×10^5 cells were inoculated into each 60-mm dish and incubated for 72 h at 33° C permitting the cells to reach log-phase growth at a concentration of about 1×10^6 cells per dish. At time 0, half of the dishes were transferred to 39° C. Two dishes each at the time of transfer and intervals thereafter were labelled with $0.5 \mu\text{Ci ml}^{-1}$ ^3H -thymidine (a), $1 \mu\text{Ci ml}^{-1}$ ^3H -uridine (b) or $0.5 \mu\text{Ci ml}^{-1}$ ^3H -L-leucine (c) for 30 min at 33 and 39° C. The medium was then removed and 10% trichloroacetic acid added. Acid insoluble material was collected by filtration and radioactivity was counted in a Beckman scintillation counter. □, Cells at 33° C; ●, at 39° C.

Co.) without added antibiotics. To isolate the mutants, 33° C was used as the permissive temperature and 39° C the non-permissive temperature. Cells were treated with 10^{-5} M N-methyl-N'-nitro-N-nitrosoguanidine (NG) which killed approximately 70% of them. The rest were grown at 33° C and added to 60-mm Falcon plastic culture dishes at a concentration of 2×10^5 per dish and incubated at 39° C for 24 h, at which time $10 \mu\text{g ml}^{-1}$ cytosine arabinoside and $10 \mu\text{g ml}^{-1}$ 5-fluorodeoxyuridine were added. The dishes also received $40 \mu\text{g ml}^{-1}$ uridine to prevent 5-fluorouracil, a breakdown product of 5-fluorodeoxyuridine, from interfering with RNA synthesis¹¹. After a further 24 h at 39° C, the medium was changed to MEM and the dishes were returned to 33° C. When clones had developed, the cells were transferred to Linbro 24-well multi-dishes. Half the cells in each clone were added to wells in dishes incubated at 33° C and half were added to the corresponding wells in dishes incubated at 39° C. The cells which grew at 33° C but not at 39° C were removed and further tested for growth at 33° and 39° C. No mutants have been isolated without NG treatment. Of more than fifty mutants isolated, one, ts-546, was found in which mitosis is blocked in metaphase at the non-permissive temperature.

The wild-type cell differed slightly from the mutant in growth rate at 33° C. The parental HM-1 cells grew at 33° and 39° C with doubling times of 20 and 12 h respectively. Mutant ts-546 grew well at 33° C with a slightly longer doubling time of 25 h (Fig. 1). When the ts-546 mutant cells were placed at 39° C, the cell number increased slightly for 2-4 h and then declined (Fig. 1). The decrease in cell number was probably a result of the cell counting procedure used, in which medium was removed before trypsin was placed in the dishes to dislodge the cells attached to the bottom. The mutant ts-546 cells arrested in mitosis (described later) tend to be loosely attached or not attached and were readily removed with the medium. No cells remained attached to the dishes after 5 d.

When 50 or 100 cells were plated per 60-mm dish, the parental wild type cells plated with >90% efficiency at 33° and 39° C (Table 1). The plating efficiency of the mutant was slightly reduced at 33° C, but at 39° C, when up to 2×10^6 ts-546 cells were plated per 60-mm dish, no clone was found (Table 1). Cell killing at 39° C was thus independent of the density of cells inoculated. Of the 10^8 cells cultured at 39° C, two revertants have been found giving a reversion frequency of about 5×10^{-7} .

Incorporation of labelled precursors into acid-insoluble material in wild type and ts-546 cells was also measured. A sample of 10^5 cells was inoculated per 60-mm dish and grown for 72 h until log-phase growth was reached at approximately 10^6 cells per dish. Half the dishes were then switched to 39°C . At intervals, ^3H -thymidine, ^3H -uridine or ^3H -L-leucine was added for 30 min at both temperatures. Incorporation of ^3H -thymidine per cell began to decrease after 4 h for the cells incubated at 39°C (Fig. 2). The decrease could be partly or totally due to the fact that as the cells entered mitosis, they were arrested in metaphase (described later) and consequently unable to enter G1 and re-initiate DNA synthesis. No change in the incorporation of the labelled material into RNA or proteins was found at 39°C (Fig. 2). The incorporation procedure eliminated any loosely attached or floating cells when the medium was removed before trichloroacetic acid was added. This may explain why RNA synthesis per cell was not decreased even though a fraction of the cells was arrested in mitosis and expected to synthesise little or no RNA¹².

Mitotic figures were examined after the mutant cells were grown at 33°C and 39°C . When the mutant cells were grown at 33°C , normal mitotic figures were observed (Fig. 3a). After the cells were shifted to 39°C , many aberrant mitotic figures appeared (Fig. 3b). The chromosomes seemed no longer to be held together by the spindle. They were scattered as in colchicine-induced 'colchicine-metaphase'¹³ (C-metaphase), where spindle fibre mechanisms are partially or totally destroyed, and the chromosomes lose their normal orientation. To distinguish the figures seen here from C-metaphase, the aberrant mitotic

Fig. 3 ts-546 cells at 33°C . Cells grown at 33°C were washed with phosphate-buffered saline, fixed with 3:1 methanol-acetic acid and stained with aceto-orcein. Arrows point to normal metaphase (M), anaphase (A) and telophase (T) in (a) and aberrant ts-546-metaphases in (b). ($\times 200$.)

Fig. 4 Change in mitotic index and percentage of mitotic cells in metaphase in ts-546 cells after incubation at 39°C . 10^6 cells in log-phase growth per 60-mm dishes were transferred to 39°C at time 0. Cells were fixed and stained at intervals. The mitotic index (a) is expressed as the percentage of cells in mitosis. The percentage of mitotic cells in metaphase (b) is defined as

$$\frac{\text{No. of cells in metaphase and ts-546 metaphase}}{\text{No. of mitotic cells}} \times 100.$$

figures induced by temperature shift are termed 'ts-546-metaphase'.

Immediately after the cells were switched to 39°C , mitotic figures (metaphase, ts-546-metaphase, anaphase plus telophase) started to accumulate. The mitotic index, or the fraction of cells in mitosis, increased from approximately 3% to more than 8% after 7 h at 39°C and decreased thereafter (Fig. 4a). The fact that the mitotic index did not increase beyond 8% was most likely due to the fixation procedure with loosely attached or floating cells lost during washing. Time-lapse photomicro-

Table 1 Clone forming ability of parental (HM-1) and mutant (ts-546) cells at 33°C and 39°C

TMTC, too many to count.

graphs demonstrated that, in a culture of ts-546 cells at 39° C, the number of round, refractile, mitotic-like cells increased continuously and subsequently floated into the medium. When a culture of ts-546 cells was incubated at 39° C for 24 h, at least 50% of the cells appeared to be rounded and mitotic-like. At the same time, few dumbbell-like figures characteristic of anaphase or telophase cells were seen (Fig. 5).

The number of metaphases and ts-metaphases increased from approximately 50% of the mitotic figures at the time of temperature switch to close to 100% 8 h later (Fig. 4b). The number of anaphases and telophases correspondingly decreased from 50% to nearly 0.

The results show that when hamster ts-546 mutant cells were switched from 33° to 39° C, the cells ceased to divide almost immediately. With further incubation at 39° C, cells were killed regardless of their density. Reversion frequency was about 5×10^{-7} . No generalised defect in DNA, RNA or protein synthesis was found at the non-permissive temperature. At 39° C the mitotic cells were arrested in metaphase and ts-metaphase, which is seen as a failure of the normal spindle fibre mechanism to hold the chromosomes in their normal metaphase orientation. The ts-metaphase figures, under a light microscope, appear to be similar to the c-metaphases resulting from colchicine treatment.

Fig. 5 Accumulation of mitotic-like cells at 39° C. Cells in dishes in log-phase grown at 33° C were incubated at 39° C for 24 h when the photograph was taken. ($\times 140$.)

Since mitotic cells generally synthesize very little or no RNA¹², one may ask that why is no reduction of RNA synthesis observed at 39° C? The cells used for measuring ³H-uridine incorporation were those which remained attached to the dishes where the maximum number of mitotic cells reached only 8% after shifting to 39° C (Fig. 4a). Consequently 92% or more of the cells used in the incorporation experiment were non-mitotic. The finding that the cells not in mitosis incorporate

a normal amount of ³H-uridine is thus compatible with the conclusion that the ts-546 cells in mitosis are blocked in metaphase at the non-permissive temperature.

Several mechanisms might account for the accumulation of mitotic cells in metaphase and ts-metaphase at 39° C. The gene controlling the production of spindle fibre proteins or microtubules could have suffered a mutation resulting in defectiveness and inability of the proteins or microtubules to orient properly at 38° C. A second possibility is that a protein holding the spindles together became defective. A third alternative is that a protein holds the spindle proteins and chromosomes together, becoming defective at the non-permissive temperature, so that the chromosomes are disengaged from the spindles. It is also conceivable that the defective protein, when normal, binds the spindles to the centriole. There is also the possibility that the synthesis of the spindle fibre proteins or other factors involved in karyokinesis failed to take place at 39° C. These possibilities are being investigated.

It is to be hoped that the isolation of temperature sensitive mutants defective in mitosis could lead to the identification of factors which are essential in mitosis. It might also be possible to identify the time during the cell cycle when these factors are synthesised. Furthermore, the possibility that mitosis can be arrested because specific factors become defective at a higher, non-permissive temperature may provide methods of arresting metaphase and controlling cell growth by specific inhibition of these factors.

I thank Dr Frederick Landa for reviewing the manuscript. This investigation was supported by an American Cancer Society research grant and a US Public Health Service Research career development award from the National Institute of General Medical Sciences.

Facilitation of Learned Resistance to Audiogenic Seizures in Balb/cCrgl Mice by d-LSD-25

ALTHOUGH conditioning techniques applied to electrophysiological behaviour are presently being used in behaviour therapy for human epilepsy^{1,2}, complete cure is still a hope of the future. Extensive reports indicate that minute amounts of d-lysergic acid diethyl amide (d-LSD-25) could be used to assist current biofeedback training and other therapies used to effect change in the EEG and seizure susceptibility of

epileptics³ and we note many studies of the facilitation effect of small doses of *d*-LSD-25 on learning and memory⁴⁻¹⁸.

Several methods, including many behavioural ones¹⁴⁻¹⁸, are known for changing audiogenic seizure susceptibility in inbred mice. Elaboration of a conditioned response is known to interfere with the occurrence of these seizures¹⁹ and exploratory activity and learning ability are positively correlated with seizure resistance in rodents²⁰, as are several factors related to stress^{14,21}. We confirmed these effects in experiments with mice in which the administration of 3.65 μ g of *d*-LSD-25, 30 min before conditioning, significantly facilitated long-term habituation and also conditioned inhibition of audiogenic seizures induced by an intense, high-frequency sound presented 1 d after the end of training.

Long-term habituation was brought about by exposing the mice to a subseizure threshold tone 1-4 d before challenging them to seize with the louder tone. This effect is related to the classical 48 h refractory period found after intense stimulation¹⁴. Conditioned inhibition of seizures was accomplished by pairing a light with brief subthreshold tones, and subsequently presenting the light 5 s before the challenge stimulus on test night.

The use of multiple exposures to improve estimates of seizure susceptibility was first reported by Fuller and Sjursen²². Henry²³ later showed that a priming stimulation of only 30 s at an early age induced development of seizure susceptibility which peaked 4-5 d later, suggesting a method of more reliable control of seizure susceptibility. In standardising procedures for Balb/cCrgl mice, we found that peak seizure incidence (88%) on day 26 after priming on day 21 was equal to the cumulative seizure incidence computed as the percentage of mice that seized at least once during four consecutive exposures on days 21, 28, 35 and 42. In our experiments, the treatment variables were introduced between days 21 and 26.

Six hundred and eighty-five mice were randomly assigned to groups by split litter design, weighed and used to test the effects of pure *d*-LSD-25 (Sandoz) given intraperitoneally (7.3 μ g ml⁻¹; average dosage 180 μ g kg⁻¹; standard dose, 3.65 μ g per mouse) on the alteration of audiogenic seizure susceptibility by experimental and control procedures which are listed below. All mice were primed on day 21 (1900 h) and tested on day 26 (1900 h). The main experimental procedures were as follows. Series 1, running to escape from the hand of the experimenter in an activity wheel at 50 m d⁻¹ on days 22-26 (1900 h); series 2, the direct effect of *d*-LSD-25 given on days 21 and 26 (30 min before priming and testing respectively) as compared with the same injected only on days 24 and 25 (1900 h); series 3, the effect of *d*-LSD-25 given 30 min before training on long-term habituation on test night induced by five 1 min alternating exposures to a subseizure threshold 10 kHz pure tone (60 dB above 0.0002 dynes cm⁻² presented repeatedly on days 22-25 (1200 h) as compared with the effect when injected 30 min before receiving 20 min continuous exposure on days 24 and 25 (1200 h); series 4, the effect of *d*-LSD-25 injected 30 min before a 15 min non-random classical conditioning session of delayed light (25 W red, diffuse bulb)-tone (10 kHz at 60 dB above 0.0002 dynes cm⁻²) pairing (ISI, 1.5 s, US, 10 s, time-out, 15 s) on day 25 (1900 h). On day 26 the conditioned stimulus (red light) was presented 5 s before the challenge stimulus (condition CS in series 4 of Table 1).

Drug controls received equal amounts of handling and of the diluent (0.9% sterile saline) and yoke stimulation. Additional control groups were included as indicated in Table 1. For series 1, controls received equal amounts of exposure to the hand of the experimenter in a fixed activity wheel, in series 2, controls were not primed, and in series 3 they received equal exposure to the experimental chamber. For series 4, experiment 1, controls received equal cyclic exposure to light-only and tone-only. Controls in experiment 2 of series 4 received identical light-tone pairing but were not

exposed to the conditioned stimulus on day 26 during challenging (Conditions CS).

All mice were primed and tested with a 90 s 10 kHz pure tone at 100 dB above 0.0002 dynes cm⁻². A concentration check after 6 months showed no change in the LSD solution kept in the dark, near room temperature.

The results are summarised in Table 1. Repeated locomotor practice significantly reduce seizure susceptibility by 24%. This effect is not strong and was not significant in a smaller sample (data included in experiment 1 of series 3) treated with *d*-LSD-25. The effect is not due to a single session of running just before testing on day 26. Earlier work with activity wheel stress and audiogenic seizures found very similar results¹⁵.

At 3.65 μ g per mouse, repeated or single doses of *d*-LSD-25 had no direct effect upon seizure susceptibility. Only one 3.65 μ g dose, however, increased conditioned inhibition and long-term habituation of audiogenic seizures in the presence of the conditioned-unconditioned and unconditioned stimulus respectively. The increase in habituation was more significant. Future work on conditioned inhibition might use more elaborate procedures to study the effects of *d*-LSD-25 on higher learning.

These results did not depend on *d*-LSD-25 being present during testing performed 24 h after injection and training. Controls showed learning occurring to a lesser degree independent of the *d*-LSD-25 state during acquisition. These results support earlier findings that low amounts of *d*-LSD-25 facilitate ongoing processes in the brain, affecting learning and memory⁴⁻¹³. Studies of the best time relationships between states and of the use of equal or preferably smaller doses to effect reverse tolerance are needed. The symptoms of overdose are well known to have effects opposite to those of lower doses⁹.

Mice exhibit the highest resistance to high-dose effects of *d*-LSD-25, as much as 300 μ g per mouse being required to produce overt changes in its behaviour²⁴. We have shown here that as little as 1% of this dose caused significant facilitation of learned behaviour which reduced subsequent seizure susceptibility. Although caution must be observed²⁵ these data may be extrapolated to the human condition on at least three grounds. Similar forms of reflex epilepsy exist between the two species (for example, startle, audiogenic and musicogenic epilepsy²⁶⁻²⁹). Acoustic stimulation has been found to be superior to intermittent photic stimulation or hyperventilation in defining the cortical paroxysmal focus in the EEG of humans with temporal lobe epilepsy³⁰. (There is reason to believe that a cortical focus facilitates the audiogenic seizure in mice.) Also, seizures in both species are subject to the effects of learning^{1-3,19}.

The facilitation effect of single low doses on learning has been reported for humans as well as several animal species in many different situations. Suggestions that *d*-LSD-25 causes undesirable side-effects, such as chromosomal damage, when used in clinically useful doses, have been refuted by investigations *in vitro* and *in vivo* in several species including humans^{3,31-37}. 'As neural degeneration and functional depression due to anticonvulsant medication are a problem³⁸⁻⁴⁰, human experimentation with low dose schedules and learning should be considered.

By comparing dose-effect data from the mouse and human it is possible to estimate the optimum dosage required to facilitate learning and memory in the human. The mouse detoxifies *d*-LSD-25 ten times faster, has a metabolic rate ten times greater and a much lower brain/body weight ratio than humans; so its high resistance to direct effects is not surprising. Overdose symptoms peak at approximately 300 μ g for the mouse²⁴ and 1,000 μ g for the human⁴¹. As 1% of this dose significantly reduced seizure susceptibility in mice through learning, the optimum dose facilitating condition inhibition of seizures in human epileptics could be as low as 10 μ g or less (that is, about 0.1 μ g kg⁻¹ as compared with the so-called moderate dosage of 1-2 μ g kg⁻¹). Further, since 100 μ g represents the anticonvulsant threshold in mice, at least 300 μ g should be required to suppress motor seizures directly in the human epileptic.

The physiological mechanisms underlying the effect of *d*-LSD-25 on brain function are relatively well understood⁸. It acts directly as an anticonvulsant when taken in high doses. Approximately 1-5 mg kg⁻¹ must be given to the mouse to increase seizure resistance independent of conditioning^{42,43}. This direct protection is related to the facilitation of motor and sympathetic nervous activity within this dose range for the mouse^{42,44-47}. High dose inhibition of synaptic transmission through the thalamus⁴⁸ is probably not a necessary part of the anticonvulsant action in mice, since all brain rostral to the inferior colliculus is unnecessary for elaboration of the audiogenic seizure sequence⁴⁹, but may be where subcortical activation of a cortical focus is necessary for the seizure to occur^{50,51}.

Bradley and coworkers⁵² showed that small amounts of *d*-LSD-25 amplify the ongoing effects of sensory collateral inputs to the reticular formation of the brainstem without directly affecting sensory input to the cortex⁵³ or directly exciting the output cell core⁵⁴ of the reticular formation. They later discovered that these effects focused attention of

the animal on to a neutral or habituated stimulus to the degree found with conditioned stimuli (where response thresholds were not affected by the dosage used) without directly arousing the animal or preventing its sleep. They suggested that in small amounts, *d*-LSD-25 increases the significance level of sensory stimuli by facilitating mechanisms which underlie attention and block short-term habituation. The inhibitory effects of attentional mechanisms in animal and human epileptics are extensively documented although they are still not fully understood⁵⁵.

Amphetamine has also been shown to facilitate learning and memory only within an optimal dose range⁵⁶ and also to reduce audiogenic seizure susceptibility at high doses^{31,42,43}. An optimal range in the dose-effect curve is a classical finding. Some drugs that facilitate learning at low doses, however, act as poisons and convulsants at higher ones (for example, strychnine)⁵⁶. Drugs chosen to facilitate behaviour therapy for epilepsy could conveniently act as anticonvulsants at high or cumulative doses while simultaneously minimising side-effects.

A recent review⁵⁷ re-affirmed past conclusions that LSD can be a safe therapeutic instrument when properly administered to suitable subjects in controlled settings. Tetrahydrocannabinol^{58,59,60} and psilocybin^{50,51} also act as anticonvulsants. This combination of facilitation of learning and memory in minute doses, direct anticonvulsant action in the upper dose range, reverse tolerance with proper scheduling, and the absence of addiction and proven side effects directly attributable to the drugs, suggests the use of psychedelic compounds as effective and safe adjuncts to current behavioural and electrophysiological biofeedback procedures presently used to treat epilepsy and a variety of other illnesses.

We thank Dr M. Gates of the University of Rochester for supplying the LSD.

Augmentation of Cytotoxic Drug Action by Antibodies Directed at Cell Surface

THE concept of attaching cytotoxic agents to tumour-specific antibodies in the treatment of cancer is therapeutically attractive. In this way the specificity of the agents would be increased and their systemic toxicity reduced. This immunochemotherapeutic approach has been successfully applied in experimental systems when the cytotoxic agent has been covalently bound to the antibody¹⁻³. Similar success has been reported with the nitrogen mustard chlorambucil, merely physically adsorbed on to the globulin fraction from tumour-specific antiserum

without the actual formation of a covalent bond⁴. It is surprising that antibody could act as a carrier for chlorambucil under these conditions, as has been proposed⁵, as the two molecules would be expected to dissociate in the *in vivo* environment. It is, therefore, probable that the increased cytotoxicity of chlorambucil in the presence of antibody is attributable to some other mechanism. The experiments described here are an attempt to elucidate this problem further.

The target cells for these experiments were polyoma-transformed BHK21/C13 cells (J₁) grown in Dulbecco's modified Eagle's medium supplemented with 10% calf serum which had been heated to 56° C for 30 min to inactivate complement. The cells were collected using a Tris-buffered saline containing 0.02% versene. An antiserum to these cells was produced in New Zealand white rabbits. Each rabbit received approximately 1×10^8 intact cells intramuscularly twice weekly for 4 weeks. The resulting antiserum contained antibodies for surface components of J₁ cells as shown by membrane immunofluorescence by the indirect method using fluorescein-labelled sheep antirabbit globulin (Miles-Serevac). The antiserum was also cytotoxic for J₁ cells in the presence of guinea pig complement (Wellcome) as shown by isotope release from cells prelabelled with radioactive chromium (⁵¹Cr); 50% of cells were lysed at a 1:320 dilution. Control normal rabbit serum (NRS) was obtained by bleeding the rabbits before immunisation. Both the NRS and the immune serum (IRS) were heat inactivated, sterilised through a 0.22 μ Millipore filter and stored

Fig. 1 10 ml volumes of undiluted calf serum were placed in lengths of Visking dialysis tubing (0.25 inch diameter), which were then arranged as flat coils and covered with 10 ml of one of the following solutions: (1) 1×10^{-6} M ³H-chlorambucil (specific activity 118 mCi mmol⁻¹) in PBS (○); (2) rabbit immunoglobulin (IgG) (Miles-Serevac) 50 μ g ml⁻¹ with 1×10^{-6} M ³H-chlorambucil preincubated on ice for 15 min (▲); (3) bovine serum albumin 50 μ g ml⁻¹ with 1×10^{-6} M ³H-chlorambucil preincubated on ice for 15 min (●). Dialysis proceeded at 37° C and 100 μ l samples of the dialysate were taken at timed intervals for scintillation counting.

at -20°C until used. Chlorambucil BP (Wellcome) was prepared just before use by dissolving a few mg in 0.5 ml of 0.5 M sodium bicarbonate, at room temperature and then immediately diluting in cold phosphate-buffered saline solution (PBS), pH 7.2.

the possibility that the increased sensitivity of the cells to chlorambucil was due to an increased rate of mitosis; (3) since it has been shown that chlorambucil in high concentrations ($6 \times 10^{-3}\text{ M}$) causes lysis of red blood cells⁷, the possibility that IRS may allow lysis of J_1 cells by lower concentrations of

Table 1 Cloning efficiency of Py BHK(J_1) cells treated with combinations of C, NRS and IRS described in text

Means \pm standard deviations of colonies in quadruplicate cultures.									
PBS	C	NRS	NRS/C	NRS-C	NRS+C	IRS	IRS/C	IRS-C	IRS+C
50 ± 2.2	38 ± 5.7	64 ± 6.8	39 ± 6.1	59 ± 8.7	39 ± 10	53 ± 16.5	14 ± 7.8	58 ± 6.8	12 ± 11

Differences: NRS/C and IRS/C, $P < 0.01$; NRS+C and IRS+C, $P < 0.02$; IRS/C and IRS+C, not significant.

The effect of chlorambucil on J_1 cells in the presence of immune serum was studied using a colony formation inhibition assay. One hundred cells were plated in 50 mm plastic Petri dishes in a 4.5 ml volume of medium with 10% inactivated calf serum. Then the cultures received one of the following additions: (1) 0.5 ml of PBS alone or containing one of the following substances: chlorambucil (C) to give a final concentration in the culture medium of $6 \times 10^{-6}\text{ M}$, or either NRS or IRS at a final dilution of 1 : 80 in the culture; (2) 0.5 ml of PBS with NRS or IRS mixed with C in the cold so that only physical adsorption of the drug to protein but little or no covalent reactions would occur⁶ (NRS/C and IRS/C); (3) 0.5 ml of PBS with NRS or IRS mixed with C and preincubated at 37°C for 24 h to allow complete reaction of the C, mainly alkylation of protein but also some hydrolysis⁶ (NRS-C and IRS-C); (4) NRS or IRS in 0.25 ml of PBS and C in 0.25 ml PBS added at the same time but separately to the dishes (NRS+C and IRS+C). In all cases the final concentration of chlorambucil and the dilution of NRS or IRS was the same. After incubating the dishes in humidified incubators flushed with carbon dioxide for 8 d, the medium was aspirated, the colonies were washed once with PBS, fixed with methanol, stained with 20% Giemsa stain and counted.

The results (Table 1) show that the cloning efficiency was the same with PBS, NRS alone, IRS alone, NRS-C and IRS-C. In those dishes that received active chlorambucil, namely C, NRS/C and NRS+C, there was a small reduction in the number of colonies. The reduction was however much greater when the drug was in the presence of IRS (IRS/C and IRS+C). Preincubation of IRS and chlorambucil in order to favour the adsorption of the drug on to antibody was not a prerequisite for augmenting the cytostatic effect of the drug.

These results corroborate, in a different system, those of Ghose *et al.*⁵ but do not support the hypothesis that they occur because the antibody acts as a carrier for chlorambucil. In fact, the identity of the effect of IRS/C and IRS+C would then require that chlorambucil associates preferentially with and binds strongly to rabbit immunoglobulins in competition with the calf serum proteins present in the medium. That this is not the case was shown by the experiment described in Fig. 1. The results show that the rate of disappearance of chlorambucil from the dialysate is the same whether or not it contains rabbit immunoglobulin, thus excluding preferential binding of chlorambucil to the immunoglobulin.

The mechanism whereby antibodies directed at the cell surface increase the susceptibility of polyoma-transformed BHK21/C13 cells (J_1) to the cytostatic effect of chlorambucil remains unknown. Several possibilities were ruled out by the following results. (1) The uptake of tritiated-chlorambucil by IRS-treated cells was not different from that of NRS-treated cells; (2) the mitotic rate of cells in the presence of IRS or NRS as determined by growth curves was the same, thus excluding

chlorambucil was considered. Cells were prelabelled with ^{51}Cr , treated with IRS or NRS together with graded doses of chlorambucil, and ^{51}Cr release was measured. While it was confirmed that these cells were lysed by $6 \times 10^{-3}\text{ M}$ chlorambucil too, there was no lysis in lower concentrations with either IRS or NRS.

Experiments using other cell systems and agents are now in progress to test the generality of this augmenting effect of antibodies on cytotoxic drug action and its possible use in cancer therapy. It is known that when tumours are associated with a well developed humoral immune response, for example in Burkitt's lymphoma⁸ and choriocarcinoma⁹, the response to cytotoxic drugs is often dramatic. We speculate on the basis of the experiments described above that in these malignant diseases it may be the binding of antibody to the tumour cells that by some means, not yet determined, is responsible for their marked susceptibility to chemotherapy.

We thank Dr F. C. Copp of The Wellcome Research Laboratories for the gift of chlorambucil BP and Mr L. Griggs of the Chester Beatty Research Institute for tritiated chlorambucil.*

Spatial Heterogeneity and Population Stability

THE ability of populations to absorb perturbations is often investigated theoretically by some variant on the prey-predator, Lotka-Volterra, equations. Usually the treatment is in terms of linearised equations and thus deals with very small perturbations from a steady state. Recently, May¹ has enlarged the scope of investigation by considering perturbations from limit cycles rather than divergence from the simple steady state. This theoretical approach assumes populations uniform in space if not in time, but much of the variability found in nature is not only in large temporal cycles but in smaller-scale spatial patchiness. This variability may be handled statistically to give, for some specified area, a mean and variance for the populations. These can be used for 'sensitivity analysis' of the output from a theory or computer model, or as a basis for stochastic treatment. In either case this variability, as a function of changes in space, is not an intrinsic part of the model. Yet much experimental work shows that populations of prey or predator with limited abilities to disperse can produce spatially heterogeneous patterns, and the scale and complexity of these patterns may have some effect on persistence of these populations^{2,3}.

The technical problem in theorising about the consequences of dispersal lies in quantifying the rate of dispersal. In the sea, this can be overcome for planktonic populations such as phytoplankton and small herbivorous copepods which are almost entirely at the mercy of water movement and yet display considerable patchiness⁴. The dominant form of motion in the open sea away from areas of strong ocean currents is turbulent lateral diffusion⁵. This diffusion is similar, mathematically, to ordinary Fickian diffusion although on a much larger scale. To study the effect of this process on populations and to include the non-linear effects, it is simplest to begin with an expansion of the Lotka-Volterra equations to include variation along one spatial dimension, x . For phytoplankton, P , and herbivorous copepods, H , the interactions can be expressed as

$$\begin{aligned}\partial P/\partial t &= aP - bPH + \partial/\partial x \kappa \partial P/\partial x \\ \partial H/\partial t &= cPH - dH + \partial/\partial x \kappa \partial H/\partial x\end{aligned}$$

Assume that at some time there are random perturbations within the limits $(0, L)$ of x , expressed as Fourier series,

$$P = \sum_{n=0}^{\infty} A_n \cos \lambda_n x, \quad H = \sum_{n=0}^{\infty} B_n \cos \lambda_n x, \quad \lambda_n = 2\pi n/L$$

then the time rates of change of the coefficients A_n and B_n are expressible in the form,

$$\begin{aligned}dA_n/dt &= A_n(a - \lambda^2 n^2 \kappa) - bC_n \\ dB_n/dt &= cC_n - B_n(a + \lambda^2 n^2 \kappa)\end{aligned}$$

where

$$C_n = 1/2(\sum_{r+s=n} A_r B_s + \sum_{r-s=n} A_r B_s)$$

The terms involving C_n arise from the non-linear interactions of P and H . When these are ignored, as in the linearised study of small disturbances, or when only one population is considered, then perturbations at any wavelength are either amplified or damped at that wavelength and it can be shown⁶ that perturbations below a certain critical wavelength will be damped out by the processes of diffusion. In other words, only large patches would be expected to persist against the smoothing effects of turbulence.

The introduction of the non-linear terms leads to entirely different conclusions. Not only do perturbations interact to cause shorter wavelength 'harmonics' (the first term in C_n) but also they interact to give 'beat frequencies' at longer wavelengths (the second term in C_n). In particular, the perturba-

tions alter the mean. For example, for the mean value A_0 of P in $(0, L)$,

$$dA_0/dt = aA_0 - bA_0B_0 - 1/2b \sum_{r=1}^{\infty} A_r B_r$$

The first two terms on the right-hand side correspond to the normal 'Lotka-Volterra' equation⁷ which produce bounded oscillations with time. The spatial variations A_r, B_r ($r \geq 1$), however, interact to alter this mean. Thus, perturbations at any wavelength can, in theory, act to displace the prey and predator from their neutral limit cycle. In this way small-scale spatial variability in the populations which, on the linearised theory, would be damped out could, by directly displacing the mean, lead to a random walk to extinction as happens with stochastic effects on the ordinary Lotka-Volterra equations⁸ without diffusion.

As it would seem that diffusion or dispersal can never be sufficient to damp out fluctuations, these theoretical effects emphasise the need for positive stabilising factors, such as functional responses⁹ acting at the average population levels. The conclusions also imply that, when considering the effects of variability within an ecosystem, it is inadequate to introduce these by studying the effects of variation of each population on a model of the average population levels of an ecosystem. This ignores the interactions which can occur spatially and which thereby introduce changes in these average levels. Although the very simple, Lotka-Volterra, equations have been used here, more complex reactions, which introduce stabilising functions but do not consider spatial changes, should still have the same inadequacies in determining the limits of stable response in the face of environmental fluctuations.

These concepts have been developed for marine planktonic communities but the principles involved should apply to populations where dispersal is a significant feature of their life cycles. For plankton it is possible to quantify the effects on stability introduced by the combination of diffusion and spatial heterogeneity and this will be described elsewhere.

Energy cost of gliding flight in herring gulls

By using the interplay of aerodynamic and gravitational forces, birds are known to travel considerable distances on fixed wings. The aerodynamics of this form of flight has been studied in the field¹⁻³ and in wind tunnels⁴⁻⁶, but the energetic cost is unknown. We report here experimental determinations of oxygen consumption during prolonged gliding.

Wild-trapped herring gulls (*Larus argentatus*) were trained to fly in a wind tunnel⁵ while wearing light-weight (10 g) ventilated head masks. From an initial sample of eight animals, only two would learn to glide consistently

TABLE 1 Metabolic rates during gliding flight in two herring gulls (calculated from oxygen consumption, using $1 \text{ l O}_2 \text{ h}^{-1} = 5.58 \text{ W}$)

Gull No.	Mass (kg)	No. of flights	Resting	Metabolic rate (W)			
				Mean	Gliding	Minimum	Mean increase
1	0.965	5	6.64 ± 0.58	12.50 ± 1.60		9.95	$1.9 \times$
2	0.859	4	6.57 ± 0.92	15.41 ± 0.81		14.71	$2.4 \times$

Values are means \pm standard deviation.

for periods of twenty minutes without flapping. All the reported data are from these two animals. Oxygen consumption was measured by drawing room air through the mask at a metered rate of 25 l min^{-1} and measuring the difference in oxygen concentration of the gas from the mask and that in room air (for details, see ref. 8). Oxygen consumption was taken as the stable minimum value maintained for at least 5 min of the 20 min test. We assume that this stable value represents steady state oxygen consumption as no increase was apparent at the end of the gliding periods. Resting measurements were made both before and after glides on birds standing unrestrained on the floor of the wind tunnel under the same conditions of temperature and illumination. Stable minima maintained over 20 min periods were taken as resting oxygen consumption levels. Food was withheld from the birds for 16 h prior to all experiments and in all metabolic calculations, R.Q. was taken as 0.8. Air speed and glide angle were adjusted to values at which the bird had minimum acceleration relative to the tunnel. For both animals this resulted in an air speed of 10.8 m s^{-1} and a glide angle of 6.5° below horizontal. The air temperature was 27.5 to 29.2° C .

Table 1 shows results from resting and gliding birds. Oxygen consumption at rest for both birds was about 1.7 times the expected standard rate as calculated from the allometric equation of Lasiewski and Dawson⁷. For one bird, gliding resulted in a mean increase in oxygen consumption to 1.9 times the resting level and for the second bird to 2.4 times the resting level.

It is interesting to compare our measurements with those taken for steady state flapping flight under similar wind tunnel conditions. Several such determinations have given an oxygen consumption during steady state horizontal flapping flight of about seven times the resting level⁸⁻¹⁰ (this ratio will probably vary as additional species are studied). Another comparison is with Pennycuik's theoretical calculations of the cost of gliding². By adding the calculated standard metabolic rate to an estimate of the power input by the pectoral muscles during gliding, he arrived at a figure of about 1.5 times the basal rate for the white-backed vulture. This provides an interesting comparison with our minimum value of 1.5 times the resting level (compare Table 1).

We conclude that gliding flight represents an increase to about twice the resting level of oxygen consumption and has a substantial energy-saving advantage over flapping flight.

Evidence Against a Genetical Component to Performance on IQ Tests

Eaves and Jinks¹ have failed to note the significance of Scarr-Salapatek's² data, which provides important evidence against the heritability of IQ performance. A straightforward overall evaluation of this study, together with a review of evidence³⁻⁷ which Eaves and Jinks consider to be more secure in establishing a genetical component to IQ performance shows that: (1) the upper limit of IQ heritability in Scarr-Salapatek's study is $15\% \pm 16\%$. This is consistent with zero heritability and directly contradicts the higher figures claimed by other studies³⁻⁷; (2) other studies⁵⁻⁷ which use identical-fraternal comparisons to derive apparently higher upper limits to heritability do not take into account the more similar treatment frequently given to identical twins. When this is adjusted for, these studies are consistent with low or zero heritability; (3) the similarity between separated identical twins, used by Jinks and Fulker³ to derive an 80% heritability estimate, can be quantitatively accounted for by highly correlated placement (ref. 8 and L. J. Kamin, Invited Address, Eastern Psychological Association, Washington DC, March 1973) with little or no genetical component.

We use the methods of Jinks and Fulker for our evaluation. The difference in correlation coefficients for identical twins raised together (MZ) and fraternal twins raised together (DZ) is

$$r_{MZ} - r_{DZ} = [G_1 + E_1(DZ) - E_1(MZ)] / \sigma_T^2 \quad (1)$$

where

$$\sigma_T^2(DZ) = \sigma_T^2(MZ) \text{ and } G = G_1 + G_2$$

In general $E_1(DZ) > E_1(MZ)$ since identical twins are treated more similarly than fraternal twins. Identical twins are of the same sex, are frequently dressed alike, given the same toys and mistaken for one another. Thus, large differences in correlation of identical and fraternal twins do not necessarily mean high heritability, or any heritability^{4,8}, and studies of MZ-DZ differences can only give upper bound estimates for G_1

$$G_1 / \sigma_T^2 \leq r_{MZ} - r_{DZ}$$

To obtain the upper limit heritability from Scarr-Salapatek's data we have, for the error in z scores of MZ twins, $\sigma_{MZ}^2 = a\sigma_{\text{res}}^2 + b\sigma_{\text{os}}^2$. The coefficients a and b are given in Eaves and Jinks¹. With $\sigma_{\text{res}}^2 = 1/(N_{\text{ss}} - 3/2)$ (ref. 9) where N_{ss} is the number of same sex pairs and similarly for σ_{os}^2 and with $\sigma_r = (1 - r^2)\sigma_z$ we compute the standard deviation of the correlation coefficient r_{MZ} . Assuming $Z_{DZ} = Z_{\text{os}}$ (this raises

the heritability estimate since in general same sex DZ twins are treated more similarly than opposite sex DZ twins) we then compute the variance, σ_d^2 , of the difference, $r_{MZ} - r_{DZ}$, $\sigma_d^2 = \sigma_{MZ}^2 + \sigma_{DZ}^2 + 2(1 - r_{MZ}^2)(1 - r_{DZ}^2)(P/(1 - 2p))\sigma_{os}^2$ where $p = 0.30$ for whites and $p = 0.34$ for blacks. For Scarr-Salapatek's Table 8 we obtain four independent estimates of the difference $r_{MZ} - r_{DZ}$ as follows: black, lower socio-economic status (SES) = -0.165 ± 0.185 ; blacks higher SES = 0.109 ± 0.184 ; whites, lower SES = -0.046 ± 0.340 ; whites, higher SES = 0.160 ± 0.110 . Using least squares the overall best fit is

$$r_{MZ} - r_{DZ} = 0.075 \pm 0.082 \quad \chi^2 = 2.4(3 \text{ d.f.})$$

or

$$G_1 \leq 7.5\% \pm 8.2\%$$

Estimating the heritability depends on the relative magnitudes of G_1 and G_2 . Previous work has used $G_1 = kG_2$ with $k \approx 1$ (refs 1, 2, 5, 6). For purposes of comparison we choose $k = 1$ and obtain

$$h^2 \leq 15 \pm 16\%$$

which is a new upper limit to the heritable component to performance on IQ tests.

This result is to be compared with other estimates⁵⁻⁷ cited by Eaves and Jinks derived from the identical approach. It is 4.0 standard deviations lower than the figure of $h^2 = 80\%$ quoted by Jensen^{5,6} and promulgated in popular accounts¹⁰. The probability of a discrepancy this large occurring by chance is less than 10^{-4} if the true heritability is $h^2 = 80\%$.

We fail to understand why Eaves and Jinks are prepared to discard this result. To do so only perpetuates the apparently common practice in this field of ignoring or failing to report evidence against the genetic hypothesis. As Scarr-Salapatek describes it "there are few published reports of null results unless a major theoretical point is at issue. I, for one, obtained the same correlation (0.61) for blood-grouped MZ and DZ twins on an individually administered test of non-verbal IQ and did not submit the results for publication (because no one would believe that MZ twins were not more similar, there were only sixty pairs and so on)"¹¹.

The apparent discrepancy between $h^2 \leq 15 \pm 16\%$ and the higher figures reported elsewhere^{5,6} is resolved by estimating the size of the 'treatment' effect, caused by the more similar treatment of MZ twins. By comparing the correlations of groups with the same G_1 we obtain pure treatment effects of expected magnitude less than $E_1(DZ) - E_1(MZ)$. From Victorin¹² $\Delta r_{DZ}(\text{male-female}) = 0.12 \pm 0.05$ and $\Delta r_{MZ}(\text{male-female}) = 0.15 \pm 0.09$. (For comparison $\Delta r(\text{males})(MZ-DZ) = 0.18 \pm 0.09$ and $\Delta r(\text{females})(MZ-DZ) = 0.15 \pm 0.05$ in the same data). Similarly from Huntley¹³ $\Delta r_{DZ}(\text{same sex-opposite sex}) = 0.21 \pm 0.09$ and from Jinks and Fulker³ $\Delta r_{MZ}(\text{boys-girls}) = 0.17 \pm 0.16$. From Erlenmeyer, Kimmeling and Jarvik⁷ we see that the range in correlations for studies of the same groups is large. For parent-child $\Delta r = 0.6$, for siblings $\Delta r = 0.5$, and for same sex DZ twins $\Delta r = 0.45$. Since in Jensen's method⁶ $\Delta r(MZ-DZ) \sim 0.35$ yields 70% heritability, these figures demonstrate that the treatment effect acting alone is enough to produce the Δr s observed between MZ and DZ twins.

We now consider the four studies of separated twins. Kamin has demonstrated gross errors in methodology and analysis in these studies but the Shield's data is still useful for a quantitative comparison of genetic and environmental models. Jinks and Fulker³ analyse this data in terms of the components G_1 , G_2 , E_1 , E_2 , and $G = G_1 + G_2$. Naming a variance component G , however, does not mean that it is genetic. A model with the substitutions $E_T \leftrightarrow E_1$, $E_F \leftrightarrow E_2$, $E_A \leftrightarrow G_1$, $E_S(DZ) \leftrightarrow G_2$ and $E_S(MZ) \leftrightarrow G$ is an environmental model formally identical to the simple genetic model where the sources of variance are: E_T , differences in treatment of identical twins; E_A , additional differences due to the different appearance of DZ twins; E_F , between pairs family differences; E_S , differences in social environment. The results are shown in Table 1.

The large value of $E_S(MZ)$ means there is a high degree of similarity in the environments of separated MZ twins. Such

TABLE 1 Comparison of Variances of Environmental and Genetic Models Based on Analysis of Shield's Data

Environmental model		Genetic model
Variance due to differences in Social environment ($E_S(MZ)$)	71% \pm 12%	Genetics (G)
Family (E_F)	0%	Family and social environment (E_2)
Within family treatment (E_T)	29% \pm 12%	Within family treatment (E_1)

a conclusion is born out by Fehr's⁸ and Kamin's analysis of Shield's data. The null E_2 in the genetic model contradicts the known fact that social environments have a large effect on IQ performance¹⁴ while the null E_F in the environmental model means that differences in the way families in the same social environment treat children have little effect on IQ performance compared to differences in the way the social environment treats children. The environmental model is actually more consistent with the data than the conventional genetic model.

In summary, we note the following. The upper limit obtained from Scarr-Salapatek's data of $h^2 \leq 15\% \pm 16\%$ ($G_1 \leq 7.5 \pm 8.2\%$) is evidence against the heritability of IQ performance. Other low results go unreported¹¹ and this lends additional weight to her results. This 15% figure and every higher estimate reported in MZ-DZ studies contains an uncontrolled environmental component deriving from the more similar treatment accorded identical twins. Estimates indicate that this effect is large enough to make other upper limits derived from MZ-DZ comparisons consistent with zero. The separated twin studies when properly analysed also give heritability estimates which are low or consistent with zero.

We conclude that the evidence used to support high heritability of IQ performance actually yields low estimates of heritability consistent with zero and not larger than the upper limit of $h^2 \leq 15\% \pm 16\%$. Zero heritability of IQ performance means that the individuals in the population all have the same genetic potential for the expression of this trait.

We thank Professor Leon Kamin for making his results available prior to publication and Professors John Gibbon, Sonia Ragir and Eugene Weinstein for critical readings of the original manuscript.

MARINE POLLUTION BULLETIN

Marine Pollution Bulletin is the only British Journal to deal specifically with this international problem. It contains news, comment and research on all matters relating to the pollution of estuaries, the sea and other large bodies of water.

The latest (November 1973) research reports include:

The Fate of Rubbish in the Thames Estuary

P. A. Board

Impact of a Power Plant on a Subtropical Estuarine Environment

A. Thorhaug, D. Segar and M. A. Roessler

Effect of Red Mud on Marine Animals

R. A. A. Blackman and K. W. Wilson

Paraffin Hydrocarbon Patterns in Petroleum-Polluted Mussels

R. C. Clarke, Jr. and J. S. Finley

Edited by Professor R. B. Clark, Department of Zoology, The University, Newcastle upon Tyne NE1 7RU, England.

Published by Macmillan Journals Ltd.

Annual Subscription £6.50 (£7.50 USA and Canada). Prices applicable only to orders starting before December 31st, 1974. Payment may be made in any currency at the current exchange rate. Orders must be accompanied by remittance. Cheques should be made payable to Macmillan Journals Ltd., Subscription Department, Brunel Road, Basingstoke, Hampshire RG21 2XS, England.

Peatlands

PETER D. MOORE, *Lecturer in Ecology, King's College, London*, and DAVID J. BELLAMY, *Lecturer in Botany, Durham University*

Provides a survey of the results of research throughout the world into the various aspects of mines and peat production. Particular attention is given to the productivity and energy budgets of the peatland ecosystem, and wetlands and their problems—both ecological and economic. 324 pages illustrated £4.00

Advances in Reproductive Physiology Volume 6

Edited by MARCUS W. H. BISHOP, *Department of Animal Husbandry, University of Bristol*

Contents: Metabolism of the preimplantation mammalian embryo; The ultrastructure of the endometrium during the sexual cycle; Pituitary Gonadotrophic Function (FSH and LH) in various reproductive states; Hormonal control of sexual behaviour in the female rabbit; Lysosomes of the uterus; Lysosomes and lysosomal enzymes in reproduction; Physiological mechanisms for the immunological isolation of spermatozoa. 324 pages illustrated £8.50

Experimental Embryology and Teratology Volume 1

Edited by D. H. M. WOOLAM and G. M. MORRIS, *Department of Anatomy, University of Cambridge*

The first volume in a new series which aims to cover a wider field than its predecessor, *Advances in Teratology*. The series will deal with normal as well as abnormal development, and will emphasise practical approaches to both basic and applied research. 136 pages illustrated £4.00

Ethology of Mammals

Forthcoming Supplements

The March 22 issue will contain the spring book supplement—a section of 24 pages devoted to reviews of recent books.

The April 26 issue will contain a section of 32 pages entitled 'Molecular biology comes of age'. The twenty-first birthday of Watson and Crick's letter on the structure of DNA will be celebrated by a set of papers reviewing the history of and prospects for molecular biology. This issue should have a special appeal to students and to scientists working in other fields.

book reviews

Watch without Mother

Separation: Anxiety and Anger. Vol. 2 of Attachment and Loss. By John Bowlby. Pp. xviii+444. (The International Psychoanalytical Library No. 95.) (Hogarth and the Institute of Psycho-Analysis: London, May 1973.) £4.50.

PSYCHOANALYSIS has been long on theory and short on experimental evidence. Dr John Bowlby, the psychoanalyst best known for his work on the effects of maternal deprivation on children, has dedicated his later career to remedying that gap. He, and the institution with which he is connected, the Tavistock Institute of Human Relations, are now trying to use the techniques of scientific research to study the way in which the human personality develops. (The institute's director, Dr Dorothy Heard, was originally trained in the biosciences.) This volume is the second of a projected trilogy in which Dr Bowlby, looking at his basic theory that the loss or prolonged absence of the mother harms the child, asks why and how?

His method is to take as primary data the observation of young children in defined situations, and then to extrapolate forwards. He sees this as a reversal of the traditional direction of psychoanalytic hypothesis-making, which is to confront a fully formed personality and then to conjecture how it got that way. Nonetheless, Dr Bowlby wants it clear that his frame of reference is still psychoanalytic. The concepts which he sees as basic to the growth of personality are separation anxiety, defence, the bonds between people and so forth which, in his view, have been ignored by the behavioural sciences apart from psychoanalysis. But he is adamantly not a classical Freudian. Instead, he has a "perspective based on a Darwinian type theory of evolution." What this means in practical terms is that he is willing to use animal behaviour as evidence and in theoretical terms that he sees certain kinds of fears as functional, of survival value to the human race, rather than as infantile or neurotic.

Bowlby's exposition, however, is more interesting than his conclusions. From assembled evidence, he shows that the strong reaction to a mother's absence is shown by babies from the age of 26 weeks onward. He analyses the findings that a single separation of 6 days or more from its mother is harmful to an infant rhesus monkey, with effects observable as much as 2 years later. ("The

only safe dose", he concludes about maternal deprivation in these monkeys, "is a zero dose.") He declares unqualifiedly that while few other predictions can be made about children separated from their parents, it is clear that when a child is threatened with being abandoned (either explicitly or obliquely, by over-hearing quarrels), the effects of an actual separation when it occurs are likely to be magnified and to persist.

He also feels on sure ground when he rejects some cherished ideas—Freud's hypothesis of 1926 that the fear of mother's absence results from the infant's learning that when she is absent, his physiological needs go unmet, and the belief held by Freud and almost everybody else that an excess of parental affection can make a clinging child. The evidence is all the other way, he says, with documentation, that overdependence is the result of bitter experience, not excess of gratification. So why does the unwilling separation from its mother or her substitute make a child respond with fear? Bowlby offers tentative conclusions and calls for more research. His hypotheses are (1) that such fear may be instinctive, (2) the infant may learn to associate its mother's absence with distress just as it learns to associate her presence with comfort and (3) an infant may learn that it is more afraid of fear-arousing situations, such as a loud noise, when its mother is absent and thus associate her absence with fear.

Bowlby once again offers a more kindly, less punitive approach to the child than is generally taken, either by the post-Victorians or the Freudians. He deplores the fact that most people still believe that a normal child should not make a fuss when its mother leaves it at school and that "babyishness" is something to be corrected. Or that something as positive as parental love for a child could cause the pathology of overdependence.

Dr Bowlby's words are so influential—he kept a whole generation of mothers home from work—that they have to be weighed not only in the light of their contribution to psychoanalytical theory but of what will be made of them by the public. The law, the schools and many parents still have scarcely a glimmer of perception that anxiety in children cannot be cured by preaching self-control. Dr Bowlby's humane—and rational—explanations of the origins of the child's anxiety need to be listened to. But at the same time he does raise

spectres of smothering, of the claustrophobic nuclear family of which Dr Edmund Leach warned in Reith Lectures a few years ago. Is a zero dose of maternal deprivation a good thing?

BRENDA MADDOX

Ethereal molecules

Molecules in the galactic environment. Edited by M. A. Gordon and L. E. Snyder. Pp. xv + 475. (Wiley: New York and London, October 1973.) £9.50.

"ALL of the elements that make up our bodies (with the exception perhaps of hydrogen) have been formed in stars. Thus each and every one of us is, in a very real and literal sense, a little bit of stardust." These words of Willy Fowler give the clue to the wide current interest in interstellar molecules for it is believed that they may be an important link in the evolution of life in the Universe. Of course even the largest molecules— $\text{CH}_3\text{C}_2\text{H}$ (methylacetylene); HCOCH_3 (acetaldehyde)—found by radio searches in the interstellar medium are a long way from the truly complex molecules which characterise living organisms. Nevertheless, since molecule synthesis must begin somewhere, it is gratifying that the first steps of this synthesis are amenable to investigation in the depths of interstellar space even if later steps are forever lost in the uncharted atmosphere or sea of some early planet. But who really knows? Ten years ago nobody would have predicted that such a rich field of interstellar chemistry lay around the corner—a veritable Black Cloud just waiting to be discovered.

In November 1971 a conference to discuss recent discoveries was held at the National Radio Astronomy Observatory in Charlottesville, USA. This book is the conference report edited by two astronomers who have been in the forefront of the radio discoveries.

In addition to the biological implications another important aspect of recent work is the interstellar chemistry of molecule formation (and destruction). Available observations give crucial information about densities, temperatures and excitation conditions in the molecule-bearing clouds. These allow some appraisal of the proposed theories of molecule formation. It is clear that a variety of processes are at work—some are surface reactions on dust grains and others are gas-phase reactions of varying complexity, but we are still far from a complete understanding of all the proc-

esses at work in interstellar chemistry. There is no indication of how complex the undiscovered interstellar molecules may be. Even so it is unlikely that DNA will ever be discovered in interstellar space.

One field of study scarcely touched upon in this volume is the use of molecular observations as probes of the interstellar medium. They have proved particularly significant in studies of dense gas clouds such as those found in the general interstellar medium, in the immediate vicinity of certain recent formed stars and in the galactic centre region.

In summary, this book provides a number of excellent review articles—especially those of Field, Iben, Litvak and Ponnampertuma, and a medley of research reports. It will be read with interest by astronomers and biologists.

R. D. DAVIES

Strong probability

Stochastic Analysis: A Tribute to the Memory of Rollo Davidson. Edited by D. G. Kendall and E. F. Harding. (Wiley Series in Probability and Mathematical Statistics.) Pp. xiii + 463. (Wiley: London and New York, August 1973.) £11.

NAMES of branches of science are often coined to express an insight into their nature, and 'stochastic analysis' is one of these. It witnesses to the end of the isolation of probability theory, to its penetration into, and its complementary illumination by, many different areas of pure and applied mathematics. Today one finds probabilistic methods cropping up in the most surprising places, just as probability theory itself now calls on mathematical tools of every variety.

Twelve years ago the University of Cambridge established a chair of mathematical statistics, and shortly afterwards moved its Statistical Laboratory from the basement of the chemical laboratories to a disused paper warehouse. In such unpromising surroundings there grew up the leading centre in Britain for research in stochastic analysis, attracting visitors from all over the world. This volume, which is to be joined by a companion on stochastic geometry, gives a good feeling for the exciting work that has gone on there. It originated in the idea of a memorial to Rollo Davidson, a brilliant mathematician whose tragic death in a mountaineering accident at the age of twenty-five deprived the subject of one of its most promising workers, and his friends of a delightful companion. Among the articles printed is posthumous work of Davidson, reconstructed from the papers which he left.

Although in one sense the book is historical, it is not backward-looking; the lines of research described are still very active, and there are many unsolved problems which pose a challenge

for the future. Nor, despite the fact that a dozen authors have contributed, does the book exhibit the miscellaneous character common in such collections; the influence of the warehouse, and of its director, runs as a unifying thread through the various papers. To Professor Kendall, and to his colleague Dr Harding, one owes a debt of gratitude for producing a book which will be of great interest not only to the specialist, but to the mathematician or statistician who wants to know what is going on in this field.

J. F. C. KINGMAN

Atmosphere and climate

Synoptic Climatology. By R. G. Barry and A. H. Perry. Pp. xvi + 555. (Methuen: London, October 1973.) £9.50.

MANY readers will have only a hazy idea of what is meant by synoptic climatology; indeed different authors have different ideas on the subject but in this volume the basic aim is to relate local or regional climates to a meaningful frame of reference—the atmospheric circulation. The authors recognise two stages in any synoptic climatological study, the determination of categories of atmospheric circulation type and the assessment of weather elements in relation to these types. Such studies cover a very broad field including long range weather forecasting on time scales from a week or so ahead to a decade or more.

The book is sensibly laid out with main sections covering history, data and analysis, synoptic climatological analysis, statistics, applications and future prospects. One of the best features is the bibliography of some eighty pages which covers much of the useful foreign literature as well as most of the modern work of the British Meteorological Office and includes works published up to 1973. I could detect no errors in the bibliography.

The volume is intended for students of advanced climatology at senior undergraduate or graduate level and for students of environmental problems. The authors have not, however, differentiated between the wheat and the chaff; they refer to important and unimportant aspects of the subject without a clear indication of which are the most essential. In chapter 2, for example, there is a good deal of obsolescent information dating from before 1950 about the frequency of cyclones and anticyclones and the tracks of depressions and only a few pages are devoted to discussion of the value of satellite pictures in synoptic climatological analysis.

Chapter 3 gives on the other hand a very good account of the various classification systems which have been devised to describe day to day weather on both regional and hemispheric scales.

Not only are the more well known classifications such as those of Lamb and the German Grosswetterlagen fully discussed but the various Russian methods are explained in a lucid manner which is not easy to do from translations of the originals which I have studied. Lesser known classification systems, such as those based on both surface and upper air conditions, for Italy by Gazzalo and for Switzerland by Schuepp, are welcome inclusions.

The chapter on statistical methods is rather patchy; the more elementary side is adequately covered but the chapter tries to cover too much ground which would be better dealt with in a suitable text book.

Since synoptic climatology is essentially a practical subject the devotion of 150 pages to applications is very reasonable; in fact this chapter could easily have been made longer. The best use has not, however, been made of the available space: there is far too much discussion about "singularities" and methods of defining natural seasons (curiously without reference to the Russian six-season system) and very little on important applications such as animal diseases, (only one reference to the extensive work of L. P. Smith) and human biometeorology.

The section on long-range forecasting gives some indication of the complex methods presently used, but does not give any clear idea of the relative importance of the different ideas. There is a fairly good section outlining the possibilities of climatic forecasting on the time scale of decades or longer and there is good appreciation of the importance of sea temperature anomalies in determining the various atmospheric modes.

The final chapter, though short, is an adequate summing up and indicates that there is a promising future for the subject in many fields. The book should certainly go a long way towards meeting university teaching needs and will be read with interest by many meteorologists. It is a pity that some of the figures are not clear, due usually to coastlines not being adequately distinguished from other lines but occasionally also to inadequate explanation; there are also a few typescript errors. Nevertheless the book is a welcome addition to the scientific literature.

R. A. S. RATCLIFFE

Erratum

In the review of the book *Immunopotential* (Ciba Foundation Symposium 18) (242, 322; 1974), the third paragraph should have started: "It seems likely that the agents useful in cancer act on the immune system" instead of "It seems unlikely . . ." as printed.

WILEY INTERSCIENCE

PHYSICAL GEOLOGY,

by Richard Foster Flint and Brian J. Skinner, *both of Yale University.*

Replaces Physical Geology by Longwell, Flint and Sanders; Reflects the revolution in earth science caused by the theory of plate tectonics, increasing awareness of the effect of man on environments and investigations of the Moon, Mars and members of the Solar System. In describing Earth's cyclical, dynamic processes, the concept of the steady-state condition (and its importance for living things) is repeatedly emphasized.

February 1974 510 pages £7.30

RADIANT HEAT TRANSFER IN A CLOUDY ATMOSPHERE,

by E.M. Feigel'son, *Institute of the Physics of the Atmosphere, USSR*

The monograph deals with the relationship between radiation and clouds and the introduction of radiant heat fluxes into problems of the dynamics of the atmosphere and cloud physics.

January 1974 196 pages £8.60
Published by Israel Program for Scientific Translations Ltd., and distributed by John Wiley and Sons, Ltd.

BRAIN CONTROL: A Critical Examination of Brain Stimulation and Psychosurgery,

by Elliot S. Valenstein, *Department of Psychology, University of Michigan.*

This new book by the well-known neuroscientist Elliot S. Valenstein traces the fascinating story of man's attempt to control his own brain. By extensively covering a wide range of topics, including the modification of behaviour and emotions in animals and man by electrical and chemical brain stimulation, psychosurgery, electroconvulsive shock treatment, prosthetic devices for the blind and the deaf, biological approaches to controlling aggression in children and adults, controlling pain and many other topics, the author has successfully succeeded in presenting an extremely scholarly and balanced text of the major attempts to modify the brain through physical interventions.

January 1974 430 pages £6.25

TRANSPORT PHENOMENA AND LIVING SYSTEMS:

Biomedical Aspects of Momentum and Mass Transport,

by E.N. Lightfoot, *University of Wisconsin.*

Provides a unified view of both biological flow and mass transport processes from a quantitative viewpoint. Concentrates on medically orientated aspects and progresses from flow to mass transfer and from defining equations to successively more complex applications.

February 1974 508 pages £12.50

AN INTRODUCTION TO MEDICAL STATISTICS,

edited by H.O. Lancaster, *University of Sydney.*

An introduction to medical statistics as applied to the scientific, rather than technological or administrative, study of medicine. Gives precise definitions, explains terms and interprets actual data from census enquiries, clinical trials and surveys and medical literature. Emphasizes understanding data on population, fertility and mortality. (Wiley Series in Probability and Mathematical Statistics: Applied Section).

£10.50

THE TOTAL SYNTHESIS OF NATURAL PRODUCTS, Volume 2,

edited by John ApSimon, *Carleton University, Canada.*

Describes some terpenoid and steroid syntheses, areas that have been the most studied from a synthetic viewpoint. Volume 1 deals with the total synthesis of a wide variety of natural products.

November 1973 766 pages £13.40

MICROPROBE ANALYSIS,

edited by Christian A. Anderson, *Hasler Research Center, Applied Research Laboratories, U.S.A.*

Studies the analysis and characterization of the microstructures of heterogeneous materials using microprobe instrumentation. Characterization is by means of morphology, chemistry and crystallography and the three main classes of instrumentation are the electron, laser and ion microprobes. Special advantages and area of application of each of the techniques and instruments are delineated.

September 1973 586 pages £13.40

ANHYDROBIOSIS,

edited by John H. Crowe, *University of California, Davis,* and James S. Clegg, *University of Miami.*

Examines the Nature of Life in a dehydrated state—the role of water in cells and how organisms adapt to survive. Editors' commentaries and author and subject indexes are included. (Benchmark Papers in Biological Concepts).

November 1973 492 pages £12.85

Published by Dowden, Hutchinson and Ross, Inc., and distributed by John Wiley and Sons Ltd.

MICROBIAL PHOTOSYNTHESIS,

edited by June Lascelles, *University of California.*

Gathers much of the available literature about microbial photosynthesis and offers an introduction to the possible methods of obtaining microorganisms with unique and unusual properties. Editor's commentaries and author and subject indexes are included. (Benchmark Papers in Microbiology).

January 1974 416 pages £11.80

Published by Dowden, Hutchinson and Ross Inc., and distributed by John Wiley and Sons Ltd.

ANIMAL COLONIES: Their Development and Function Through Time,

edited by Richard S. Boardman and Alan H. Cheetham, *both of the National Museum of Natural History, Smithsonian Institution,* and William A. Oliver, Jr., *US Geological Survey.*

Examines the fundamental nature of metazoan colonies, reviews much of the existing literature and provides new morphologic data from both fossil and modern animals. Papers on sponges, coelenterates, bryozoans and graptolites are included.

December 1973 618 pages £18.75

THE NATURE OF THE STRATIGRAPHICAL RECORD

Derek V. Ager

Based on Professor Ager's observations in many parts of the world, this book takes a new look at the earth's history as recorded in the rocks. Mingling scientific comment with academic humour he presents a series of original and controversial propositions and challenges some of the assumptions that limit the views of many stratigraphers to their own particular areas of interest. His arguments are well illustrated with diagrams and photographic plates and though primarily for geologists, this book will also be of interest to teachers of physical geography.

£2.95

RECENT EARTH HISTORY

Claudio Vita-Finzi

Dr Vita-Finzi demonstrates the advantages of basing earth history on quantitative dating in its own right, rather than as an appendage of stratigraphy. Original and clearly written, the book may provoke disagreement but it is logically argued and will stimulate discussion among students and teachers.

£3.00, paperback £1.50

matters arising

Haem deficiency and chain synthesis

SIR—The results reported by Giglioni *et al.*¹ on the differential effect of haemin on α and β chain synthesis are interesting. The authors conclude that only α -chain synthesis is stimulated by haemin. This contrasts with the conclusions of others^{2,3} that in a cell-free

that the selective effect of haemin acted at the level of translation, supports our earlier hypothesis explaining the relative depression of α chains. In haem-free cell-free systems, globin synthesis is inhibited after several minutes. This has been shown to be due to a soluble factor which inhibits the initiation of globin chains⁸⁻¹⁰. As α chains are normally initiated at a

Controlled use of nucleolus organisers

SIR—Macgregor has proposed that only some of the nucleolus organisers present act as the templates for transcription of rRNA in somatic cells, for the amplification of ribosomal genes (rDNA) in oocytes, and for repeated replication of rDNA in polytene chromosomes¹. This hypothesis evades the usually accepted requirement for a compensatory increased use of one organiser if the other one is defective or missing. There must, however, be regulatory devices to limit such usage, for example, a quantitative control of transcription, which do involve compensatory changes, and so the hypothesis provides no genuine economy of assumptions.

As in many other eukaryotes, a large proportion of diploid cells in *Xenopus* tadpoles have two nucleoli, both of which are engaged in RNA synthesis simultaneously^{2,3}. This is the evidence, overlooked by Macgregor, that both organisers are normally transcribed. As tadpoles which have only one organiser and form one nucleolus in each cell still achieve a normal rate of rRNA synthesis, it is hard to avoid the conclusion that the rate of transcription of the solitary organiser has doubled. Even fragments of organisers are active in heterozygotes, where they form miniature nucleoli⁴. Macgregor's hypothesis concerning transcription has thus a very limited application, being identical to the concept of latent organisers and known only in some interspecific hybrids. This allelic repression of one organiser has long been suspected to indicate a control system in plant hybrids⁵, but its molecular aspects are better demonstrated in mammalian cell hybrids⁶ and *Xenopus* hybrids⁷. These examples all provide evidence of compensatory changes occurring under a transcriptional control which does not discriminate between identical organisers nor apparently reduce their activity much below the normal rate,

TABLE 1 Relative rates of α and β chain synthesis by reticulocytes of patients suffering from haem deficiency disorders

Condition	No.	Mean $\alpha:\beta$	Effect of exogenous haemin
Congenital sideroblastic anaemia	3	0.5-0.8	0.85-0.90
Acquired sideroblastic anaemia	6	0.7-0.81	0.90-0.98
Lead poisoning	4	0.4-0.7	0.8-0.91*
Lead <i>in vitro</i> (1.5 $\mu\text{g ml}^{-1}$)	15	0.75-0.8	0.95-1.05
Iron deficiency	6	0.82-0.94	—

The α and β chains were isolated from globin prepared from unpurified whole cell lysates after a 60 min incubation with ³H-leucine.

* Observations on the reticulocytes of two patients.

system the stimulatory effect of haemin on protein synthesis is non-specific but is consistent with work, previously reported from this laboratory⁴⁻⁶, on the relative rates of synthesis of α and β chains in reticulocytes of patients who were haem deficient.

In 1971, reticulocytes of patients with congenital and acquired sideroblastic anaemia were found to show a low $\alpha:\beta$ ratio⁴. Later a similar depression in $\alpha:\beta$ ratio was found in children with acute lead poisoning⁵; an effect which could be produced by incubating normal reticulocytes in the presence of lead⁶. In all three situations the $\alpha:\beta$ ratio reverted to unity on addition of exogenous haemin. The results from all these four studies are summarised in Table I. Although these results contrast with observations of Tavill *et al.*⁷ using rabbit reticulocytes, we conclude that in human reticulocytes which are haem deficient, synthesis of α chains is depressed more than β chain synthesis. Thus, haem must have a differential effect upon the synthesis of these two chains⁴.

The conclusion of Giglioni *et al.*¹

slower rate than β chains¹¹, their initiation might be more sensitive to the action of the inhibitor.

Yours faithfully,

as the presence of extra organisers in polyploid and aneuploid plants results in extra nucleoli and a proportionate increase in RNA^{8,9}.

Many of these examples can be repeated in terms of amplification, so it is only reasonable to suppose amplification is regulated in a similar manner to that outlined above for transcription. Macgregor¹ argues to the contrary, but lacks evidence; his observations on polyploid oocytes are ambiguous on this point and I doubt if his results on spermatocytes are even pertinent.

Similarly, when applied to polytene chromosomes, Macgregor's hypothesis is only a possible but unnecessary complication to the control mechanism envisaged by Spear and Gall¹⁰.

obituary

V. C. A. Ferraro

V. C. A. FERRARO, who died on January 3, 1974, had been Professor of Applied Mathematics at Queen Mary College, University of London, since 1952; he expected to retire from his chair later this year. He had earlier (1947-52) been professor at the University of Exeter.

When he came to Queen Mary College the Department of Mathematics had six members; there are now three separate departments of Pure Mathematics, Applied Mathematics, Computer Science and Statistics, with a total of thirty-five lecturing staff. Professor Ferraro directed this expansion with energy and foresight, encouraging the growth of algebra, magnetohydrodynamics and astrophysics, the theory of computation and statistics.

He was best known for his share in the Chapman-Ferraro theory of magnetic storms, and for his discovery of the law of isorotation in cosmic masses. The Chapman-Ferraro theory was first advanced in 1930, when Ferraro was a

research student, and he returned to develop aspects of it over many years. The theory ascribed magnetic storms to streams emitted from the Sun into otherwise empty space, and the recognition that the solar wind flows all the time has meant that considerable modifications have later proved necessary. Moreover, the theory was a theory of the initial phase of a storm only; the type of ring current required to explain the main phase was not identified until much later. The essentially valuable new idea introduced in the theory was in its recognition that a solar stream must be regarded not as a collection of individual particles, but more nearly as a perfectly conducting fluid, able to modify the geomagnetic field by pushing the field-lines in front of it. The theory also introduced the idea of a magnetospheric cavity, though a temporary one.

The law of isorotation (1937), later much used in the theory of star formation, asserts that in a cosmic rotating mass of ionised gas penetrated by a magnetic field the angular velocity rapidly tends to become constant along

a magnetic field line. This result, like those of the theory of magnetic storms, seems today an almost obvious illustration of the principles of magnetohydrodynamics (MHD). But these principles were not understood when Ferraro made his discovery; he can fairly be claimed to be one of the pioneers of MHD.

In the postwar years Ferraro did much to encourage research in MHD, by his own example, by organising regular seminars and by the writing of a book on the subject with Plumpton (1961). He also is known for his book on Electromagnetic Theory (1953). He was a person of continuous activity; this activity was a little circumscribed after a heart attack in 1965, but he was publishing papers on the solar wind and related subjects up to the end.

But he will be remembered most in the College for his old world charm and personal courtesy, which is best conveyed in the words of one of Queen Mary College's cockney waitresses "He was a real gentleman, he was".

He leaves a widow and one son.

Announcements

Awards

The Trustees of the Lady Tata Memorial Trust invite applications for Fellowships and Scholarships for research on leukaemia, in the Academic Year beginning October 1, 1974.

The prizewinners of the Feldberg Foundation awards for 1974 are Professor G. R. Brindley FRS, Honorary Director of the MRS Neurological Prostheses Unit, at the Institute of Psychiatry,

and Professor P. Karlson, Physiologisch-Chemisches Institut der Universität, Lahnberge.

Errata

In the article 'Effect of Muscle Stretching on Tension Development and Mechanical Threshold during Contractures' by H. Gonzalez-Serratos, R. Valle and A. Cillero (*Nature new Biol.*, **246**, 221; 1973) paragraph 10, line 2 should read 'depolarisations produced with solutions containing 80 to 190 nM K⁺...'. Reference 2 should read volume 117 not 177.

In the article 'The Fluorescence of Quinacrine Mustard with Nucleic Acids' by Ritva-Kajsa Selander and Albert de la Chapelle (*Nature new Biol.*, **245**, 240; 1973) the labelling to the ordinate of Fig. 4 should read 'Fluorescence units at 514 nm' not 'Fluorescence at 514 nm (F)'. In Table 1 the heading of columns 2 and 3 should read 'Fluorescence units at 514 nm' not 'Fluorescence (F) at 514 nm'. The last sentence in the legend to Table 1 beginning 'Fluorescence was expressed...' should be deleted. The name of the first author should be Ritva-Kajsa Selander.

No-one wins

WHAT did the general election in Britain mean—and what does it portend? British readers, worn out with journalistic analyses, will have to bear with us for a week for the sake of our overseas readers.

Hardly anyone in the political world can be very pleased by the present indecision. Mr Wilson heads a Labour Party whose number of seats falls short of the 318 needed for an absolute majority. Mr Heath, having gone to the country early to seek a strong mandate to deal with threats to his counter-inflation policy, found the country unresponsive to him. Mr Thorpe, having done wonders in making a Liberal revival look credible and worth voting for, gets 20% of the popular vote and only 2% of the seats in Parliament.

The campaign has been surprisingly moderate and serious in character. The central issue on which Mr Heath called the election was the deadlock between the government and the miners' union over pay increases, and it is clear that Mr Heath originally hoped that the country would see him as a moderate, fighting off union extremism. His motif has been 'firm but fair', repeated so often and so similar to the motif 'frei aber froh' of Brahms' Third Symphony that one was surprised Mr Heath, a cultured man, did not use the opening of that symphony to herald his electioneering appearances. Words become codewords in elections and 'firm' clearly was meant to signify 'tough on the unions' so here was an opportunity for a bitter, divisive election reviving all the class conflicts that periodically wrack the country. That this did not happen appears to have been due to two factors: the two major parties perceived that a doctrinaire battle would have allowed the Liberals to take the middle ground where the real majority always lies, and Labour was able to broaden electoral issues to the whole economic scene. Neither major party has been very explicit about what it would do for the miners, but it could be inferred that whatever the result, miners would get substantial raises, through some quasi-judicial process from Mr Heath or through some great emotional gesture from Mr Wilson.

What do the results portend?

The parliamentary system is about as close to deadlock as possible. Suddenly the much vaunted British system for maintaining two party democracy has creaked, for no leader can now ignore the Liberals and other parties which have led a shadowy existence for so many years. Liberals and Nationalists are at least relatively attractive partners for a coalition, less so the eleven Protestant Ulstermen dedicated to bringing down the tentative attempts at cooperative democracy in Northern Ireland.

Unfortunately, the national skill for compromise is poorly exercised in putting together coalitions. Labour

in particular still has bitter memories of the thirties when a coalition nearly annihilated the party. Both major parties have been hurt by the swing to the Liberals, but Mr Wilson can soldier on for maybe a year or more with the grudging support of the Liberals and Nationalists, and then turn to the electorate with a good chance of gaining an absolute majority. This Mr Heath must have perceived for he initially refused to resign and has attempted to put together a government of his own by courting the Liberals.

Much, however, must now change politically. The Liberals could well force electoral reform. The Nationalists could well force devolution of power on many issues to regional parliaments. Most important, if the grip of the two major parties, both so clearly identified with class distinction, can be loosened, it is possible that in the next fifty years Britain, still grossly class ridden, can develop a more equitable society. Neither party is able to achieve that at present.

100 years ago

IN a recent number we intimated that the Perthshire Society of Natural Science had interrogated the Parliamentary candidates for the county and city of Perth as to their opinions on the questions of State help to Science, a responsible Minister of Education, and the promotion of Scientific Exploring expeditions.

Answers—favourable, we are glad to say—were returned at the time only by the two Conservative candidates, one of whom, Sir W. Stirling Maxwell, is now M.P. for Perthshire. We are now glad to give place to the somewhat tardy reply, addressed to the secretary, of the Hon. Arthur Kinnaird, Member for the City of Perth:—"I, Pall Mall East, 18th Feb. 1874.—Dear Sir,—I was surprised to find copied into a London paper from a Scotch journal the questions put in your letter of the 29th January last, with the statement that they had not been answered by me. The fact of my being, as I believe I am, one of the patrons of the Perthshire Society of Natural Science should have been, it appears to me, a sufficient guarantee of my approval of the objects of your institution; and my active co-operation with Capt. Wells in his efforts during the last session of Parliament to obtain the sanction of Government to a proposed grant for the furtherance of Arctic exploration, further approves my appreciation of the objects you advocate, in my willingness to support State expenditure for well-devised schemes of scientific research and educational purposes.—Yours truly, A. Kinnaird."

Decisions about the European computer industry

In deciding whether to approve more funds for Compagnie Internationale pour l'Informatique (CII), the French member of the European computer grouping Unidata, the French government is having to weigh up the long term prospects of, for example, an alliance with an American company. Professor A. S. Douglas, Professor of Computational Methods at the London School of Economics and Past President of the British Computer Society examines the underlying issues.

EUROPEAN cooperation, as has been recently demonstrated in Washington, is often difficult to achieve. Nowhere had this proved more true than in computing, and the latest report of the problems of CII is only one further manifestation of the phenomenon.

Case for indigenous industry

There are some very obvious reasons why an indigenous computer industry is desirable in any country. Industry, commerce and government itself are all coming increasingly to depend on the efficiency and speed of computers in handling clerical tasks, plant control and planning studies. The industry is already the third largest, in terms of turnover, after oil and aircraft. At least one company in the industry, IBM, is highly profitable. Thus each government, nervous of the effect which foreign control of this key resource might have on its own efficiency and that of local industry, seeks to protect itself and its 'charges' as best it can, and local interests seek to participate in the profits which should flow from a new and growing industry.

Since the computer industry has its roots, in the main, in the United States, the general fear of external interference may be made more or less pointed by the political climate existing between any country and the United States. The more concern over political implications, the more urgency is there to avoid undue dependence on technology from the United States; the stronger the local interests in the industry, the more concern there is to build up local industry under some form of protective umbrella which will hamper United States activity locally.

The arguments which have led many governments, including those of Britain, France, West Germany and Japan, to subsidise and protect their local interests against the supposed 'threat', are, of course, valid concerning neighbouring governments which may be thought to hold an important card in the industry. Thus cooperation is apt to be approached in a spirit of suspicion. Only if the external threat to a group is deemed strong enough, or if there is an obvious pay-off for all, is it likely that the suspicions will be overcome and a real measure of cooperation take place.

Arguments for cooperation

Setting aside the strength (or otherwise) of this 'threat' from the United States—on which opinions will clearly differ—and the rather more general sentimental arguments in favour of cooperation within Europe, the primary arguments for cooperation are commercial. Computers, even minicomputers, are relatively complicated machines, both to

build and to maintain. Good design makes for reliability and ease of maintenance but such design only results from the incorporation of experience. Experience is gained from use, and is the more quickly learned the more machines are sold and used. Thus quantity production leads not only to reduced unit costs, as with all products, but also to a more sharply convergent 'learning curve' towards the lower unit costs themselves.

There is, then, a double prize for achieving quantity production, and this can only be done in a large market. Europe is a fast-growing computer market and will, no doubt, in time become similar in size to that in the United States. A truly European marketing strategy, if pursued without political hampering, ought to be sound commercially. A sensible selection of points of attack on the dominance of the United States ought to succeed, whether or not governmental support is available, provided the companies concerned are at least as well managed as their competitors. All companies are, however, somewhat vulnerable in the course of their early developments and when a major investment in say, a new range of computers is being made, so perhaps there is a case for support. What is really needed is access to the whole European market on a basis of parity in each country and the price for this seems to be 'multinationalisation' of the firms concerned.

Because I believe that there is sound commercial sense in aiming to achieve a freer market situation, I would suppose that governments will press forward with collaboration—though obviously on the best terms each feels it can get for its own protégées. Probably, therefore, a solution will be found to the problems of CII and cooperation with Siemens and Philips will continue.

Professor A. S. Douglas

Britain

Meanwhile the British position requires careful consideration to see what is likely to be in the interest of British industry as a whole. Clearly ICL is an important part of the industry and its interests must be considered. But there are important sections in peripherals, minicomputer terminals, software and bureau operation, where government action can have equally important influences and where money is to be made both at home and abroad by good husbandry. So far, the Department of Trade and Industry has tended to pay very little attention to these areas and has concentrated its policy around the support of ICL alone. Recently there have been welcome signs of change, and it is to be hoped that a broader view will be taken in the future.

international news

Behaviour modification in the limelight

Colin Norman, Washington

IN the past few weeks, the topic of behaviour modification has been accorded considerable public attention and a good deal of newsprint in the United States. The sudden burst of publicity stems from two separate decisions by government agencies to withdraw support from potentially embarrassing projects, and the affair bears witness to the strong and growing public concern about research projects involving human experimentation.

The first government action to arouse interest was a decision by the US Bureau of Prisons to terminate a controversial project at a federal psychiatric prison at Springfield, Missouri. Called Start (an acronym for special treatment and rehabilitation training), the project involved rewarding good behaviour by granting so-called privileges to the inmates. The project was terminated, according to the Bureau of Prisons, because it was too costly, but the decision came after a group of inmates had filed suit in the federal courts, contending that Start violated their constitutional rights because it constitutes cruel and unusual punishment.

The second, and perhaps more important, episode was an abrupt decision by the Law Enforcement Assistance Administration (LEAA) to withdraw funds from projects involving "psycho-surgery, behaviour modification—including aversion therapy—and chemotherapy". According to LEAA Administrator Donald E. Santarelli, the decision was taken because the agency lacks the skills to monitor such research, and in any case, the projects are peripheral to LEAA's business of providing assistance to state and local law enforcement activities.

Those two incidents seem to indicate that the Nixon Administration has taken a critical look through its programmes involving human experimentation and has decided to weed out the more questionable among them. Unfortunately, however, that is not the

case and the two actions by themselves clear up none of the questions about the acceptability of behaviour modification, nor do they indicate any new policy throughout the Administration on human experimentation.

For one thing, the debate has so far been completely unencumbered by a definition of what constitutes behaviour modification, and for another, the two decisions were taken for bureaucratic, as opposed to ethical, reasons. But the actions will have beneficial consequences, and if nothing else, the public attention indicates that the concern over safeguards on human experimentation—a concern which owes much to the revelation in 1972 that a federally sponsored research project had denied treatment to a number of poor black men who were known to have syphilis—is making it much more difficult for questionable projects to carry on unnoticed.

As for the LEAA decision, Santarelli announced that his agency is getting out of the business of medical research and behaviour modification entirely, and that proposals for funding such research in future will simply be referred to the Department of Health, Education and Welfare. The agency, he said, is now conducting a search of the projects it has been funding, to see which fall into the forbidden category.

Given those statements, it may reasonably be asked what controls the agency has been applying to safeguard the rights of subjects in research projects it has been funding. The answer is pretty obvious from the fact that the agency does not even know what research projects it has been supporting, although its own guidelines dictate that each project involving medical research "should receive individual and prior approval by LEAA". Most LEAA money is provided in the form of block grants to state and local governments, and thus the agency is not always fully aware of every individual project receiving its support.

Without a definition of what constitutes behaviour modification, it is difficult to know exactly what LEAA intends to scrap, but some of its projects are clearly in jeopardy. It has been funding a project in Puerto Rico, for example, which involves the use of drugs in an attempt to see whether there is a link between criminality and brain damage. The agency has also

been supporting a project in Pennsylvania which is designed to test B. F. Skinner's theory of reward conditioning in the treatment of young offenders. Those projects will clearly lose their LEAA funds, but there is a whole grey area of projects that cannot easily be categorised, and whose future is therefore uncertain.

LEAA's decision is also likely to have hammered a nail into the coffin of a controversial proposal to establish a Center for the Study and Reduction of Violence at the University of California, Los Angeles. The centre which was proposed in 1972 and which was embraced by Governor Ronald Reagan in his State of the State message in

LEAA Administrator Donald E. Santarelli

January 1973, had applied for a \$750,000 block grant from LEAA, and for a similar amount from the State of California. LEAA had already consulted HEW on the matter, but it will now wash its hands of the proposal and the ultimate decision on whether to fund the centre will probably rest with HEW.

The centre has already caused a huge amount of controversy at UCLA and it has come to national attention largely through the work of a Washington-based public interest group called the Children's Defense Fund. Proposals for the centre, which have undergone many revisions since they were first put

forward in 1972, include investigations of the use of cyproterone acetate, a controversial so-called castration drug, on sex offenders; investigations designed to determine whether there is any correlation between abnormal electrical activity in the brain and violent behaviour; studies looking for correlation between criminal behaviour and the possession of XYY chromosomes; and biofeedback and aversion therapy for sex offenders. The centre's plans, which have been drawn up by its proposed director, Dr Louis Jolyon West, have been strongly criticised, by both public interest groups and by individuals who have examined them. Given the publicity that has already been attracted by the centre, it seems unlikely that it will be able to get through the network of review committees that HEW requires for research involving human subjects.

HEW, in fact, now has under consideration a proposal for strengthening its control of human experimentation (see *Nature*, 246, 239; 1973), and the Congress is considering a bill to strengthen the rules even further. Thus the LEAA decision will have the effect of shifting research into an agency where it will be reviewed rather critically on ethical and legal grounds.

As for the decision of the Bureau of Prisons to scrap the Start programme, that action is less far reaching, but nevertheless it is an important indicator that even the officials who operate the federal prison system, who have been heavily criticised by prisoners' rights organisations and other groups, are not unaware of the embarrassment potential of questionable human experimentation.

Last week, in fact, Mr Norman Carlson, Director of the Bureau of Prisons, and Dr Martin G. Groder, the Warden-designate of a medical research prison being built at Butner, North Carolina, were called before a committee of the House of Representatives to explain the bureau's behaviour modification studies. Both men denied that any aversion therapy is being carried out in federal prisons, and they agreed that the Start programme had some faults, chief of which is that the prisoners selected to take part had no choice in the matter, thereby violating one of the chief safeguards in any human experimentation: informed consent.

The committee was anxious to know about the plans for the Butner facility, and about the safeguards that the bureau will provide to ensure that research carried out there does not violate prisoners' rights. According to Groder, the prison, which will be capable of housing up to 340 prisoners, will be partly a medical treatment facility for prisoners with severe mental disorders, and partly a correctional research facility. As far as the

latter function is concerned, it will test various psychological and therapeutic methods of behaviour control, such as group therapy on the Synanon drug treatment model, and those that are found to be successful will be applied throughout the prison system.

Groder specifically stated that "none of the methods (of behaviour control) already preliminarily chosen or being considered favourably, involve the methods of modern-day torture known as aversive conditioning, specifically the misuse of drugs, electric shock or psychosurgery". That was greeted with favour by the committee, but the Congressmen were less impressed with the proposed methods for ensuring that prisoners taking part in the research programmes do so entirely of their own accord.

Groder made clear that those who will take part will have every opportunity to decline to take part, or opt out once the programme has started. But he also said that the prisoners selected to have a chance of taking part will all be within a few months of being considered for parole. At that stage of his incarceration, a prisoner is likely to do whatever he can to help assure his release—including taking part in a research project.

Nevertheless, the upsurge of public interest in safeguarding subjects of human experimentation should ensure that the Butner facility is kept under close and critical surveillance.

Vets make pay claim

John Hall

FIVE hundred veterinary surgeons employed by government departments in Britain have started a work to rule in support of a pay claim calculated to be in the region of 20%. The claim is vaguely defined and long delayed because the pay of veterinary officers is tied to that of scientists in government service, who are themselves waiting for action on a protracted and bitterly pursued claim. In hard cash terms, however, the vets are clear about their long term aims: an increase of £900 to £1,000 a year in the pay of grade one veterinary officers, currently earning £2,996 to £4,004.

Their industrial action threatened the government's brucellosis eradication programme and day-to-day essential work like the implementation of food orders and quarantine supervision. They gave a specific undertaking that they would not halt any work whose interruption would cause a health hazard,

either to animals or humans: the last time they threatened industrial action in similar terms, swine vesicular disease broke out the next day and their disruptive plan was called off.

Announcing the work to rule, the vets' union, the Institution of Professional Civil Servants (IPCS), painted a picture of a sadly declining profession, manned by middle-aged gents whose retirement will leave the service in a state of virtual collapse. Mr Cyril Cooper, Deputy General Secretary of the IPCS, said the service is operating on a manpower 30% below the required complement and that in the next eight or nine years something like half of the vets in government service would have reached retirement age, leaving the department in a "disastrous" situation.

Recruitment has almost come to a standstill because of the disparity between the salaries of vets employed by the state and those in private practice. In 1972, 300 graduates entered private practice, compared with eight entering government service, and of the 8,500 vets at work in Britain the state service accounts for a diminishing group of less than 5%. Although an arbitration tribunal in 1968 expressed doubts that a cash settlement would improve recruitment, and a more recent working party suggested that changes in the structure of the profession might offer a solution, the vets themselves have no doubt that the disastrous recruitment figures can only be reversed by a salary review on a grand scale.

They point out that since the beginning of 1971, the cost of living index has risen 28%, and wages generally have risen by 41%. Their own salaries have risen by between 19.5% and 26.5% depending on grading and so, in order to bring state vets back to their former position, a relativity increase of about 20% is needed. At present, salaries paid to the three grades of Government Veterinary Officer are: grade one, £2,995 to £4,004; grade two, £2,616 to £3,312; and Divisional Veterinary Officers, £4,240 to £5,912. They suggest that their future salaries should be compared with those of doctors, who can expect between £6,700 and £7,200 a year, and with dentists, who may be £600 below that level.

The Veterinary Service, they say, has operated for years on the good will of vets who were willing to cut corners and do work which they were not strictly required to do. But the goodwill is now in scarce supply, and since governments of different political complexion have shown themselves to be equally bad as employers, the vets thought they could only make their feelings known by applying pressure based on industrial action. They will do no overtime, give no lectures outside working

hours, take no work home, take time off in lieu of any weekend work they have to do, refuse to use their home telephones for official calls and stop doing jobs which ought properly to be done by an officer of a higher grade. Unless there's an outbreak of foot and mouth, that is.

Soviet breeder reactor accident

from our Soviet Correspondent

RECENT unofficial reports, apparently based on data from United States satellites, indicate a serious accident to the Soviet fast breeder reactor BN-350, which formed the heart of the new town of Shevchenko on the Mangyshlake Peninsular on the Caspian Sea.

The reactor was designed to power a desalination plant producing more than 100,000 cubic metres of fresh water a day and was intended to transform the desert shore of the Caspian "where even the camels look weary" into a modern, industrial model township with a population of 80,000, complete with parks, fountains and avenues of shady trees. The town was clearly intended to be a showpiece, and was accordingly named after the nineteenth century Ukrainian poet Taras Shevchenko, although the "drowsy waves, sky unwashed and dirty" and the "worthless sea" to which he was exiled was not in fact the Caspian but the Aral. Shevchenko was, however, a figure of world renown (even meriting a statue in Washington DC) and was considered a suitable eponymous hero for what was intended to become a showpiece of national and international importance.

Reports of the disaster pose some interesting problems when compared with the official publicity handouts. According to the Novosti Agency, the reactor, which was commissioned on September 27, 1972, was officially "launched" on July 16, 1973. Shortly afterwards an *Izvestia* correspondent visited the station and described in glowing terms the reactor with its control centre "like the bridge of an imaginary spacecraft". An influx of visitors was clearly expected—a special display showing a mockup of one of the fuel elements was exhibited in the entry hall. Even the *Izvestia* correspondent, however, noted the hazards of the "exotic coolant", molten sodium: but he stressed that special safety measures had been incorporated in the design.

The BN-350 was designed to operate on the three-circuit principle: in the first circuit the sodium flows directly round the fuel elements (steel "pencils" containing 6 mm pellets of uranium-235-

enriched uranium) and itself becomes radioactive, giving off heat through the steel heat exchanger walls to the molten sodium and the second circuit which is heated to 450° C. The sodium in the second circuit then heats the water in the third circuit in the usual way, producing a nominal 1400 tonnes of steam an hour. In all, the reactor has six such three-circuit loops. The total thermal power of the reactor is rated at 1 million kW (1GW) which can be divided between electricity generation and desalination as required. Initially, an optimal regime of 150,000 kW of electricity and 12,000 tonnes of desalinated water a day was envisaged.

The reports and rumours of damage suggest that something has failed in the cooling channels—though whether this refers to the first or second sodium circuit is not definite. Clearly, either could cause the "large fire" which the satellite data are said to indicate: damage to the first circuit, however, would be far more serious, involving a considerably greater radiation hazard.

The most curious feature is the date of the alleged disaster. That generally

mentioned is July 1973, shortly after the official "launching". But as late as August 21, 1973 the Novosti agency issued a three-page report on the BN-350, the "atomic heart" of the Mangyshlake Peninsular (a length of coverage normally given only to matters of major international importance). Either the satellite dating is incorrect, or the Novosti agency was particularly late in releasing information, or some attempt was made at a cover-up operation—a not unlikely contingency, in view of the prestige attached to developments at Shevchenko.

Chemists think about energy

IN Britain a group of top university chemists has been talking with scientists from Imperial Chemical Industries, British Petroleum and the Department of Energy in order to define long term prospects for evolving alternatives to fossil fuel supplies. The meeting followed an initiative by Professor R. Mason, Chairman of the Science Board of the Science Research Council (SRC), and among the academics brought in for the talks were Sir George Porter, Professor Sir Derek Barton and Professor Geoffrey Wilkinson. Similar discussions are likely to take place in other departments of the SRC, and a joint communique is expected in a month or so. In the meantime the Chemistry Study Group has issued the following statement:

"The Science Research Council has a broad responsibility for promoting research of 'timeliness and promise' which, together with its involvement in postgraduate education, can be expected to provide advances in fundamental scientific knowledge. However, within this general remit, the council is concerned to assess the balance of its funding pattern in relation to national needs or priorities. In common with many other scientific research funding agencies throughout the world, events of the past three months have caused it to take a new look at topics of research which may have a bearing on the energy situation.

A Chemistry Study Group of the Science Board (Secretary, Dr S. M. Mellows) has recently debated preliminary views of possible chemical innovation which might be applicable in the general context of energy supply. The Study Group accepted that any short term solutions to the problems in this area will most probably be based in industry, or, say, the Department of Energy rather than in the universities or polytechnics and, therefore, concentrated on longer term prospects such as the need for synthetic fuels in the year

Switched off in academe

A SUGGESTION that universities might lose their exemption from the working of the three-day week in Britain has been made in a memorandum issued to heads of departments and administrators at the University of Birmingham. Asking that the use of academic buildings in the evening and at night should be discouraged, the university's Estates and Buildings Officer, Mr J. H. Fathers, told members of staff that he was making the request as a result of an urgent message from the University Grants Committee (UGC).

"On Monday morning" the memo reads, "I received an urgent telephone call from the UGC telling me that the Department of Energy had contacted them to say that representations had been made about the excessive use of electricity in educational establishments. The department inferred that if this continued universities might be specifically placed under the regulations of the three day-week Statutory Order".

The UGC said it had no knowledge of an urgent telephone call and the Department of Energy denied making any inference that universities might be subject to the Statutory Order.

2000. Contributions to the Study Group's discussion from the wider chemical community would be welcomed.

The Study Group's first concern was to assess the possibilities for the fixation of atmospheric carbon dioxide. There was general agreement that emphasis on a biological photosynthesis would be justified, the photochemical synthesis, perhaps metal-catalysed, of organic molecules such as methanol or formic acid appearing to be a challenging and reasonable objective. Indeed much more knowledge generally of the photochemistry of related simple systems, such as the carbonate ion, is needed. The organometallic chemistry of carbon dioxide was discussed at some length and it was recognised that there had been little work directly related to this area; the Study Group's view might be summarised by saying that, although much would accrue in the general field of synthesis, it was not obvious at this time that homogeneous catalytic fixation of carbon dioxide was either technically feasible or economically viable. New developments of heterogeneous catalytic alloys could aid the separation and fixation of atmospheric carbon dioxide but an alternative technology based on molecular sieves appeared to be economically unattractive. It appeared that a single step conversion of methane to higher hydrocarbons or to higher alcohols would be of considerable interest to industry in the short term.

It was accepted that the further development of photovoltaic and photogalvanic cells should be of high priority and that the latter have potential for energy storage. The development of efficient fuel cells, similarly, is of importance but, in view of the heavy industrial investment in this area, SRC's interest should be restricted to well-defined new ideas such as alternatives to platinum electrodes. The low (about 80° C) temperature storage of hydrogen by both organic and inorganic systems emerged from the discussion as a promising area of enquiry while coordination of organic synthetic methods with solid state physics could provide new approaches to the development of the very elusive high temperature superconductor.

The Study Group emphasised that overdependence on nuclear energy for future needs, without heavy investment in research devoted to the utilisation of solar energy, could be hazardous. Of course, heavy investment in new research in these areas will require examination of the technological economics in relation to possible alternative methods. The Study Group will meet again to review any changes in the pattern of research activity and development which might originate from the chemical community as a whole."

Physicist, heal thyself

Michael Stone, East Berlin

Albert Einstein

THE mind boggles at the idea of an opera about somebody as unobtrusive and, generally, devoid of drama as Albert Einstein. The man acknowledged as this century's greatest scientist may have wrought a revolution in modern physics and astronomy, he may have shared responsibility for the development of nuclear research, but his own life was singularly free of anything approaching the sensational. His only personal experience of something nasty happened in 1933, when his books were among those burnt on Goebbels's orders and some Nazis wrecked his study in Berlin. Soon after, he emigrated to the United States where at Princeton University, he continued his studies. In August 1939 he wrote his famous letter to President Roosevelt which is said to have initiated the American nuclear research programme.

In East Germany, where "Einstein" has just had its world première at the Deutsche Staatsoper, mathematics are regarded as almost an Olympic discipline, with annual regional and national competitions, culminating in mathematical championships at different age levels throughout the Socialist countries. Fortunately for the rest of us Paul Dessau and his librettist, Karl Mickel, were more interested in the conscience of Albert Einstein and the success or failure of his endeavours as a pacifist and humanist. Dessau—for many years Bertolt Brecht's closest musical collaborator and friend—combined this subject with an ambition to revive the traditions of the popular musical theatre, from which have sprung such comic figures as the Shakespearean

fool, the harlequin, and Papageno. So he embedded the three acts showing up the relationship between politics and science—first in Nazi Germany, later in the United States—in a comic opera frame, with a prologue, two intermezzi and an epilogue.

Hans Wurst, a traditional comic character in Germany, makes a brief appearance to introduce the opera's basic idea: since science depends upon those in power, scientists ought to develop a social consciousness to make sure that their work serves humanity. In the first entracte, Hans Wurst, (which means as much as Jack Sausage) is thrown to a huge crocodile, symbolising Nazi Germany, but manages to save himself by the expedient of telling the beast a joke until outsize tears of laughter roll out of its eyes. The same trick does not seem to work during the second intermezzo—the crocodile now stands for the America of President Truman and Senator McCarthy—and he is gobbled up. In the end, a resurrected Hans Wurst balances delicately along the edge of an enormous razor, telling us how much he enjoys being alive.

In between such shenanigans we are treated to a semi-historical essay on the role of Einstein and other scientists under Hitler and in the US, the conclusion of which is that Einstein destroys his latest findings to prevent them being misused as, in his opinion, the discovery of nuclear fission had been perverted to blot out Hiroshima.

If this sounds like dry stuff, it isn't. Dessau is a fox who knows exactly how to garnish his score with musical titbits—here a melodious quote from Bach's Toccata, there a series of percussion effects—so that the ear craves for more. The singing is recitative rather than arioso, the orchestra relies more on the brass and the woodwinds, while the strings function mainly in parody; another pointer to Dessau's critical detachment towards the hero of his opera: Einstein was a lover of the violin.

In her production, Ruth Berghaus's scenic humour—she is Paul Dessau's wife and succeeded Helene Weigel as head of the Berliner Ensemble—well matches her husband's playfulness. In the sets of Andreas Reinhardt she provided Theo Adam (looking quite astonishingly like Einstein himself), Peter Schreier, and Reiner Süss (as two other physicists, one of whom makes his peace with the Nazis, while the other lands in gaol) with ever new stage arrangements, ensuring a pace and a high level of acting.

A silent summer in Washington State

Colin Norman, Washington

THE US Environmental Protection Agency (EPA) has given the go-ahead for what could be the most extensive use of DDT in the United States since the pesticide was banned in 1972. After much soul searching, EPA Administrator Russell E. Train announced last week that DDT can be used this summer to control an infestation of Douglas fir tussock moths, whose larvae have already munched their way through nearly a million acres of fir forests in the Pacific northwest. Although Train said that his decision was reached "reluctantly", he had little choice in the matter.

The moth, which is endemic to the forests of Washington State, Oregon and Idaho, suddenly began a population boom in 1970, and has been eating up an increasing area of foliage ever since. Such infestations usually end in the third year from natural causes, chief of which is a virus infection which spreads through the eggs in the winter and kills off the larvae when they hatch in the summer.

But this population boom failed to follow the three-year pattern, and so timber producers, farmers and the US Forest Service (part of the Department of Agriculture), petitioned the EPA to lift the ban on DDT in order to spray the larvae when they hatch in late May and early June.

The agency was forced to capitulate to demands for DDT for a variety of reasons. First, it refused to accept a similar petition last year on the grounds that the infestation would be wiped out by natural causes, without any help from pesticides. When several hundred acres of denuded trees starkly underlined the moth's refusal to follow past trends, the EPA was made to feel rather embarrassed. Another unfulfilled prophecy this year would be even more embarrassing and would add considerable impetus to attempts by a few Congressmen to strip some authority from the EPA.

Second, there are no alternative pesticides on the market which are known to be as effective as DDT in controlling the moth—a fact which Train last week blamed on the Forest Service because its research and testing programmes "have been almost totally inadequate—to the point of dereliction". And finally, the EPA was under court order to make a decision on DDT use by March 1, which is too early to tell whether there is indeed any chance of a virus infection killing off the pest this year.

The EPA was, of course, reluctant to allow use of DDT on such a large scale because it does not want to open the floodgates to pleas for special treatment for other pest infestations. Thus Train made clear last week that "my approval of this contingency request should in no way be viewed as a departure from the principles of EPA's June, 1972 order cancelling most uses of DDT. I remain personally convinced that the use of DDT represents a significant risk to ecological systems and that its use should be avoided wherever possible".

Train says that he has, in fact, extracted a promise from the Forest Service that DDT will only be used if necessary. In other words, if laboratory and field studies indicate that the population will be wiped out in some areas from virus infection, then the DDT canisters will remain unopened. The first indications of how the virus infection is progressing will come in the spring when egg masses collected last December are hatched in the laboratory.

If it turns out that DDT will be needed—and it can safely be assumed that the Forest Service will leave little to chance—then the EPA has laid down some fairly stringent rules. Spraying will begin when the eggs begin to hatch in late May, and end by the beginning of July. The pesticide will be applied by helicopter, but an unsprayed buffer strip must be maintained along streams and rivers, no spraying can take place in winds greater than 6 miles an hour and public warnings must be placed in all areas to be sprayed.

Apart from being somewhat embarrassed that their predictions of an imminent collapse in the tussock moth population failed to materialise last year, some EPA officials are also annoyed that DDT spraying has become necessary at all. One official pointed out last week that although the US Department of Agriculture itself banned use of DDT on forested areas in 1968, the department has failed to sponsor an adequate programme to develop alternative pesticides. It was only last summer, in fact, that large-scale field tests of alternatives were conducted, and even then no comparative tests with DDT were conducted. Consequently, EPA has no statistical evidence on the efficacy of DDT.

Train has therefore required, as a condition for approval of DDT use this year, that the Forest Service must undertake a "fully funded, comprehensive research effort on tussock moth control which will support registration of effective and environmentally acceptable alternatives to DDT next year".

Medical museum to move?

Fiona Selkirk

EXHIBITS from the Wellcome Trust's History of Medicine Museum may soon find a new and permanent home in the Science Museum. The Wellcome collection, assembled by Sir Henry Wellcome, contains many fine examples illustrating medical and social history, some early microscopes of excellent quality, fearsome yet interesting surgical instruments and about 200 pestles and mortars, in addition to Sir Henry's more personal collection of horse brasses and the like. The vast medical collection is very valuable and well worth exhibiting.

For many years the Wellcome Trust has been reorganising the museum and the library associated with it, and it has finally come up with a proposal which, with approval from the Department of Education and Science (DES), will mean the wholesale removal of the museum collection, but not the library, to the care of the Science Museum. (Specimens from the History of Medicine Museum can be seen in a current exhibition at the Science Museum, and in July more exhibits will be included in a display commemorating the bicentenary of the discovery of oxygen.)

Unfortunately, it seems that the Science Museum will have to do what the Wellcome Trust is forced to do at the moment—store between 85% and 90% of the collection—but if the proposal is accepted and all goes according to plan, by the end of 1976 there will be a gallery with 10,000 square feet of floor space, for a permanent exhibition of medical history.

At present, the students of medical history who use the facilities of the Wellcome museum and library have full access to the museum specimens in store. A spokesman for the Science Museum said that if all goes ahead, it is hoped to provide the same, and possibly even better, facilities—although, of course, without immediate access to the library.

The DES, which will have to approve the plans for financial reasons, has been kept informed but there have been no definite talks about the final proposal yet.

The Wellcome Trust awards grants for scientific, medical and clinical research, primarily in areas which do not receive large amounts of money from such grant-awarding bodies as the Medical and Science Research Councils. Of a total of nearly £2 million allocated in grants in 1972-73, about £350,000 (18%) went to history of medicine, but the trustees thought that no more

than £250,000 of that allocation could be spent on the museum and library. The target for 1973-74 is £365,000, of which about £90,000 will go in grants and to the units for the history of medicine at Oxford, Cambridge and University College London. It seems that the advisory panel feels that as the trustees wish to devote more funds in future to the promotion of study in the history of medicine the remaining £275,000 this year, and, possibly relatively less subsequently, will not be sufficient to finance the upkeep and development of both museum and library. The panel thinks it is important to develop the latter as a major source of information, not only about medical history but also about more modern medicine.

Museum collections have to be catalogued, maintained and well exhibited, all of which require time, effort and money. The trustees obviously believe that they cannot provide these and so justify the permanent loan of their collection to the Science Museum. There, they feel, the collection can have the care and attention it deserves.

This may be so, but the transfer of what was part of a charitable institution to the care of one funded by public money, regardless of the initial financial assistance proposed by the trust, must come under close DES scrutiny, especially when the time comes that the Science Museum needs more space for its total, ever-increasing collection.

Cooperation in coal research

John Wilson

Discussions now in progress between the National Coal Board (NCB) and the Office of Coal Research in Washington should lead to closer collaboration between Britain and the United States on research into better ways of using coal. Mr Leslie Grainger, NCB Member for Science, says that an agreement may soon be reached which will allow Britain access to the results of American research.

Naturally, the NCB's position at these discussions would be greatly strengthened if it were undertaking a substantial development programme of its own. The Board needs to set up pilot plants to test processes already studied in the laboratory and if this were done Britain could form a very useful partnership with the United States.

Formal proposals for such development work were to have been made to Lord Carrington, Secretary of State for Energy, but they have been delayed by the general election. The arguments in

favour of setting up the pilot plants are so strong, however, that they will probably be accepted by whichever party is returned to power.

The urgency with which Mr Grainger views these development plans may be judged from the massive increase in the money he thinks they deserve. In November last year he felt that about £20 million would be sufficient for the next five years. Now, barely three months later, he believes that perhaps twice that amount should be spent. That is the sort of money, he says, which must be made available—and quickly—if British industry is to compete in this new technology by the mid 1980s; the Office of Coal Research has already received \$400 million.

The processes which the board wants to see developed to the pilot plant stage include the gasification, liquefaction and fluidised bed combustion of the coal. It has already carried out much of the preliminary research on these projects and American interests have used its facilities. The Environmental Protection Agency, for example, has successfully burnt American coals in a fluidised bed combustion system at the NCB's Stoke Orchard Laboratories, Cheltenham, in some cases paying entirely for specific tests.

The Office of Coal Research, too, has been studying fluidised bed combustion systems at Leatherhead, Surrey, in conjunction with British Petroleum. It hopes to use the knowledge gained here to build a pilot plant at some 30 MW in the United States. The board would like to match this effort with a similar scheme of their own, possibly at Grime-thorpe, Yorkshire, where suitable back-up facilities are already available. This would cost approximately £2 million. Another alternative would be for the board to persuade the Americans to build their larger plant in Britain.

But in any case, Mr Grainger believes that much of the future development of fluidised bed combustion will take place in the United States because American electricity production, unlike British, is expanding. Fluidised bed combustion would thrive on an expansion of generating capacity based on a low grade fuel, and it can also greatly reduce the emission of both sulphur and nitrogen oxides in the flue gases. The keener edge to the environmentalist lobby in the United States and vast reserves of low grade coal combine to make fluidised bed combustion a more attractive proposition there.

The NCB hopes that any technical information gained by the United States in its development of fluidised bed combustion, or any of the other processes, will be re-exported back to Britain. Clearly, this sort of cooperation is the

only sensible way for industrial societies to solve their energy problems.

Family planning: a safer pill

Sally Owen

A new 'pill', containing an ultra-low dose of hormones, is expected to set a new standard of safety for oral contraceptives. Ovranette, which has been medically approved by the Family Planning Association, contains only one-third the amount of hormones in existing low-dose pills.

John Wyeth and Brother Ltd, manufacturers of the new pill, consider the lower hormone content to be an important step forward in oral contraceptive formulation, in line with the recommendation of the Committee on Safety of Drugs in 1969 that oral contraceptives should not contain more than 50 µg of oestrogen.

For some years now a small increase in the risk of blood clotting has been associated with the oestrogen in oral contraceptives. It is felt probable that doses lower than 50 µg a day make this increase even more minute. Following the committee's recommendation several low-dose contraceptives were brought to the market, most of them containing 50 µg of oestrogen.

Ovranette contains 30 µg oestrogen and 150 µg progestogen, which means that a monthly intake of about 11 mg oestrogen is reduced to 3.78 mg. This new pill should reduce the hazards of blood clotting not only because of its low oestrogen content but also because of the low dose and special nature of the progestogen involved.

Ovranette contains a progestogen called norgestrel which is not converted to oestrogen in the body. In fact it is actively anti-oestrogenic, reversing some of the changes brought about by oestrogen. It is thought therefore that the increase in blood clotting will be reduced even further.

One of the problems posed by low-dose oral contraceptives has been the unacceptable levels of breakthrough bleeding or spotting between normal menstrual periods. In clinical trials Ovranette compared well with other combined oral contraceptives, in that the incidence of intermenstrual bleeding was low. The cycle length among trial patients was invariably 28 days, with an almost unchanged menstrual flow. Other side effects, such as feelings of nausea, breast tenderness and depression, were less evident in trial patients who had been taking a pill containing larger amounts of hormones.

news and views

Even small meteoroids are fluffy

EVER since the enormous advances made in radar during the Second World War, scientists have been using radar techniques to study meteors. Most of the pioneer work was carried out at Jodrell Bank, but nowadays the world is dotted with radar research stations busily analysing the echoes returned from the columns of ionisation left behind by ablating meteoroids and relating these echoes to the physical parameters of the particles.

In an important article in a recent edition of the *Journal of Geophysical Research* (78, 8429; 1973), Verniani of the Istituto di Fisica dell'Atmosfera del Consiglio Nazionale delle Ricerche, Bologna, Italy analyses the physical parameters of 5,759 faint radio meteors recorded at Havana, Illinois in 1962 under the Harvard Radio Meteor Project. A system of six radar stations has been operated at Long Branch, Havana at a frequency of 40.92 MHz with a peak transmitted power of around 2 MW. Trains of pulses transmitted from the double trough antenna at the main site were reflected from the electron columns produced by meteoroids in the upper atmosphere (at heights of around 90 km) and observed at a series of five remote sites. These remote sites were connected to the main site by microwave links, the echoes being displayed on oscilloscopes and recorded on film.

The Fresnel pattern produced as the incident meteoroid moves through the antenna beam is used to determine the meteoroid velocity, and the measurement of the echo amplitude yields the electron line density (the number of electrons per unit length along the train). Each of the Fresnel patterns received at the different stations furnishes a value of velocity and line density at a particular time. Velocity can be measured to $\pm 5 \text{ km s}^{-1}$. Deceleration can be obtained from the variation of velocity with time and, by fitting a parabola to the values of line density, the maximum line density and the total number of electrons in the train can be calculated. Measurements of the zenith angle of the apparent radiant and the altitude of the echo points can be used to find the height of the reflection point from the echo range. The deduced ionisation curve gives the beginning and end height of the meteor train. The use of a few assumptions allows the computation of the original mass of the meteoroid when it was outside the Earth's atmosphere, the radio magnitude, the meteoroid density and the ablation coefficient (this coefficient relates the rate of mass loss to the deceleration; it is a function of the heat of fusion of the meteoroid material and the degree of fragmentation. Measurement of the coefficient gives a vital clue to the chemical composition and the physical structure of the meteoroid). It is this multiplicity of data about individual meteors that makes the observations taken at Havana and this work of Verniani's so important in extending knowledge and understanding of these meteoroid particles.

Verniani finds that the 5,759 radio meteors analysed (mean mass of $1.6 \times 10^{-4} \text{ g}$, and radio magnitude $+8.2$) have a mean geocentric velocity of 36 km s^{-1} and decelerate at the rate of 13 km s^{-2} on hitting the atmosphere. These meteoroids produce electron trains of length 11 km containing around 2×10^{16} electrons, the electron line density maximising at a value of $3 \times 10^{10} \text{ cm}^{-1}$. This maximum

ionisation occurs at a height of 92 km, the beginning height being 95 km and the end height of the train 88 km.

How do these observations tie in with other work on meteors? First, the mean density of the meteoroids is found to be 0.8 g cm^{-3} , and even more important this density is independent of mass in the range 10^{-6} to 10^{-3} g , suggesting that meteoroids have a porous, loosely conglomerate structure similar to that found for photographic and visual meteoroids having masses 10^6 times greater (see Verniani, *Space Sci. Rev.*, 10, 230; 1969). This favours a cometary origin for these particles as opposed to an origin as asteroidal collision debris, a process which would produce particles of much higher density. Verniani also finds that sporadic and shower meteors are very similar, indicating that the cometary origin of most meteoroids extends right down to 10^{-6} g .

Does the low value for the meteoroid density provide an indication of the structure of comets? The 'gravel bank' model of Lyttleton (*Comets and their Origin*; Cambridge University Press, 1953) has comets consisting of a cloud of widely spaced, small, rocky particles whereas Whipple (*Astrophys. J.*, 111, 375; 1950) postulates that comets have nuclei, these being a conglomerate of dust particles bound together by solid ices. Solar heating leads to the formation of a porous dust crust surrounding a central dirty iceball; this crust then breaks up irregularly to produce meteoroids, the low densities of the meteoroid being caused by their spongy texture, the holes in the sponge having been filled with ice when they were in the cometary nucleus. So the low density can be easily accounted for by Whipple's model; with the 'gravel bank' one would have to postulate that the gravel was itself in a low density form and this would have repercussions on the ease with which comet tails are formed. These particles, however, could be easily produced if comets are accreted from interstellar clouds by gravitational focusing. The constancy of density with mass indicates that micrometeoroids, particles of masses less than 10^{-6} g which by radiating away their heat energy float to ground and do not ablate, could be 'fluffy' and of low density whereas previously these particles were thought to have densities around 3.5 g cm^{-3} , the larger radio and visual meteoroids simply being made up of collections of these micrometeoroids.

The low density value for radio meteors is further supported by the results obtained by Verniani for the train length. The mean train length of 11 km is much shorter than was theoretically expected when meteoroids were thought to be solid, compact, stone or iron particles which simply dissipated the energy obtained from the impacts of individual air molecules by surface vapourisation of the meteoric material. The short train values lead Verniani to the conclusion that these small radio meteors often fragment, this being the same conclusion that Jacchia drew from his observations of faint photographic meteors and that Jones and Hawkes (*Nature*, in the press) draw from their work on very faint (8th magnitude) "image intensifier plus television" meteors observed at the University of Western Ontario. It seems that all meteoroids between the mass limits of 100g and 10^{-6} g are porous, fragile, crumbly objects made up of loosely conglomerate spongelike material; they all originate in comets and it is to be expected that the mean velocity of the meteoroids is independent of mass, a fact which unfortunately cannot be checked with data from radio meteors because of the height-ceiling selection effect inherent in the technique.

D. W. H.

Synthesis of ideas on early man

from a Correspondent

IN New York recently an attempt was made to bridge the gap between the palaeontologists who find and describe hominid fossils and those who seek to interpret them. A week-long conference (January 26 to February 2) was sponsored by the National Science Foundation to deal specifically with African Plio-Pleistocene hominids, the aim being to consider the fossil evidence, identify the outstanding problems and to formulate research strategies.

The first part consisted of public presentations of the evidence by the discoverers of the fossils. W. W. Bishop (Bedford College, London) began by presenting the chronological and faunal framework for the East African sites. The physical data on chronology, both isotopic and palaeomagnetic, combine with faunal correlations to provide a formidable backcloth for the hominid remains. He emphasised the primary, but not always infallible role of physical dating methods; it was the incompatibility of the fauna with the early dates from Kanapoi in Kenya that led to an eventual revision of the isotopic dating evidence. The situation in East Africa is in sharp contrast to that in South Africa where, although faunal correlation data are being accumulated,

there is a total lack of physical data on chronology.

There was unanimous scepticism about the use of geomorphological evidence to date the South African cave sites. It was felt that uncertainties about the dates of inception of planation cycles, the conflicting evidence from deep-sea cores, documentation of highly variable erosion rates and the influence of various lithologies on nick-point progression make such estimates, based on geomorphology, unacceptable as primary evidence. Hopes for adequate dating of these sites currently rest on fission track and palaeomagnetic studies. Bishop also presented the hominid remains from the Baringo basin (Kenya) and B. Patterson (Harvard University) wittily explained the context of the Kanapoi and Lothagam sites, and in doing so showed a healthy reluctance to elevate his hominid fossils to a position above that of the other fauna. He told of how the Kanapoi site was found as the result of a 'Sunday excursion' for which his field expeditions are apparently notorious.

M. D. Leakey (Olduvai Gorge) showed, albeit unintentionally, what a profound influence the painstaking archaeological, palaeontological and geological studies at Olduvai have had on the standard of field and laboratory work at other sites. F. C. Howell (University of California, Berkeley) and R. E. F. Leakey (National Museums

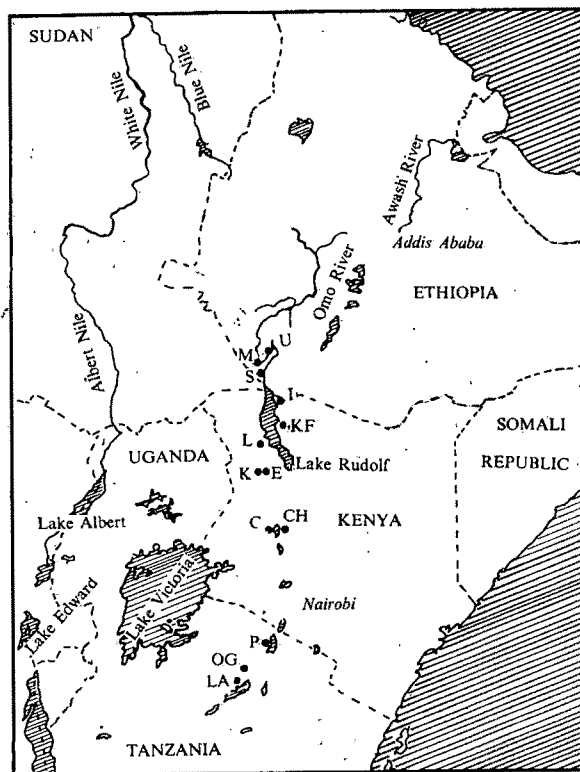

of Kenya) showed how successful this sound methodology can be when applied to the extensive fossiliferous exposures in the lower Omo Valley and in the area east of Lake Rudolf. There is apparently at Omo, as at Olduvai, evidence for an environmental change about midway in the sequence and this may be an explanation for some of the inconsistencies that exist in the isotope dates and the faunal evidence between Omo and East Rudolf.

The evidence from the South African cave sites was reviewed by C. K. Brain (Transvaal Museum) in a presentation that was perhaps the highlight of the meeting. Recent excavations at Swartkrans have revealed a new stratum, the orange breccia, and evidence of solution channels in the outer cave breccia. It is now known that SK15, one of the 'Telanthropus' mandibles comes from this channel fill and is probably not contemporaneous with the other hominid fossils. The possibility that other hominids were associated with similar channels may vitiate the importance of the South African hominids as being a sample from a limited time range and thus being better indicators of early hominid variability than the more temporally separated East African sample. Brain's elegant, and beautifully illustrated experiments using captive cheetahs and the companion investigations of leopard lairs may explain the curious differences in skeletal preservation between bovids and primates at the cave sites.

The recently prospected fossiliferous exposures in the Awash Valley in north-east Ethiopia were described by D. Johanson (Case Western Reserve University). Faunal correlations indicate an age of about 3 million years for the exposures at Hadar which have yielded hominid leg bones and a cranial fragment. Fragmentary though some of these specimens are, the excellent preservation of other vertebrate fauna suggests that these will not be the last hominids found at Hadar.

The remaining four days were held in the comfort of the Wenner-Gren Foundation. Sessions were devoted to morphology, demographic aspects, cultural evidence, patterns of diversity and implications of taphonomic evidence for behaviour patterns. Of the current research problems differences in methodology were the most evident. Views polarised into those who considered that it was necessary to establish patterns of morphological variability before phylogenetic and functional interpretations of the hominids could proceed. Others considered that examination of the material should be preceded by hypothesis formation about broader patterns of hominid behaviour and variability: suffice it to say that this

Map of some of the Plio-Pleistocene hominid localities in eastern Africa. M (Mursi), U (Usno), S (Shungura) Formations, lower Omo basin; I, Ileret sector; KF, Koobi Fora sector of East Rudolf area; L, Lothagam; K/E, Kanapoi and Ekora of lower Kerio drainage; CH, Chesowanja, Baringo basin; K, Kanam; P, Peninj, Natron basin; OG, Olduvai Gorge.

matter was not resolved! Opinions differed about the role of multivariate statistics, the criteria for establishing population diversity, the association of culture with any particular hominid group, the interpretation of bone 'tools' and the significance of differences in endocast morphology; in fact few 'stones' were left unturned.

Despite differences in approach, perhaps an uncomfortable level of broad agreement was reached about the existence of cranial, dental and postcranial morphotypes (though one suspects that for some participants there were too many cranial morphotypes to fit the teeth or postcranial material!). Future research problems that were identified include more comparative work on endocranial morphology, dental wear patterns and postcranial variability and further research into the implications of dental eruption patterns of hominines and current taphonomic studies for hominid behaviour.

This conference successfully brought together workers whose research approaches are different, but whose common aims are to discover more about the structure and behaviour of early man. This meeting complemented the workshop conference held in Nairobi in September 1973, which attempted to synthesise the results of work at Omo and East Rudolf. The publications resulting from these two meetings will attest to the growing scientific maturity of hominid studies and show the success of the international and multidisciplinary approach to hominid palaeontology which has been a feature of the research both at Omo and at East Rudolf.

Are accretion disks stable?

from a Correspondent

THE stability of accretion disks in binary X-ray sources comes under critical review in an article by Lightman and Eardley in a recent issue of *Astrophysical Journal* (187, L1; 1974). The accretion of material by a compact object (a neutron star or a black hole) from its companion in a binary star system is thought to be the main source of power for the luminous X-ray sources that have been discovered within our galaxy during the past few years. Because of the rotation of the binary system, transferred material is forced by the conservation of angular momentum initially to form a disk around the compact object. Differential rotation and viscosity, in the disk, transfer angular momentum outwards, allowing the matter to spiral inwards, liberating its gravitational potential energy as it does so. If the compact object is a neutron

star, most of the energy is liberated at the surface of the star itself, where the accreting material crashes into it. But, if the compact object is a black hole, then all the luminosity comes from the disk, and the matter arriving at the inner edge of the disk is swallowed quietly by the black hole. Thus for accretion by a black hole, widely speculated to be the case for the X-ray source Cygnus X-1, the stability of the accretion disk is an all important matter.

The most uncertain element in all models of accretion disks is the viscosity—ordinary molecular viscosity is far too small, and authors usually invoke turbulence or magnetic fields. A common (*ad hoc*) assumption is that the effective kinematic viscosity (with dimensions of length²/time) is roughly equal to the vertical thickness of the disk (the supposed size of a typical turbulent eddy) times some constant fraction of the sound speed (since supersonic turbulence would be rapidly dissipated). The difficulty arises in the inner regions of the disk where radiation pressure, rather than ordinary gas pressure, dominates the vertical structure. In this region, it is unclear what the 'sound speed' relevant to turbulent motion should be, and it is usually assumed to be that dictated by the radiation. Lightman and Eardley, however, have demonstrated that, in this part of the disk, this assumption about the viscosity is not consistent with the disk being in a steady configuration. They show, moreover, that if the disk is forced initially to conform to the previously calculated 'steady' configuration, it evolves secularly, breaking up into rings. The reality of these rings is, however, questionable, since their formation depends on being able to start in a supposed 'steady' situation, which has already been shown not to be self-consistent.

The reason for this 'instability' is fairly simple. The assumptions mentioned earlier lead to the conclusion that in this part of the disk, the viscous stress is inversely proportional to the surface density of the disk. Thus, if a small region of the disk has a lower than average surface density, the viscous stress, and hence the radial velocity, there will be higher than average, and so the surface density will decrease still further.

The authors suggest two possible alternatives. First, if one assumes rather than the 'sound speed' relevant to turbulent viscosity is that given by the gas pressure, then the resultant steady accretion is self-consistent. Second, if the assumptions made are roughly correct, then the idea of a steady accretion disk must be abandoned. The observed variability of the source Cygnus X-1 on timescales as short as milliseconds might lead credence to this idea. In any

event this contribution serves as a timely reminder to theoretical astronomers that '*ad hoc*' assumptions which seem to work should not have too great a trust put in them.

Darwin glass related to tektite fall?

from our Geomagnetism Correspondent

THE material that has come to be known as Darwin glass was first recognised and described just 60 years ago by Suess who found large quantities of it along a north-south track some 3 km to the east of Mount Darwin in Tasmania. About 50 years later, geochemical studies and the discovery that the glass contains coesite led to the view that the Darwin glass must have been formed by impact—a conclusion which was strikingly confirmed two years ago when Ford (*Earth Planet. Sci. Lett.*, 16, 228; 1972) discovered Darwin Crater, a circular depression with a diameter of about 1 km lying some 4 km or so to the east of the most southerly of Suess's deposits.

It is now known that there are far more examples of glass in the vicinity of Mount Darwin than Suess had realised; and with the aim of confirming the genetic relationship between the original occurrences and the more recently discovered crater glasses, Gentner *et al.* (*Earth Planet. Sci. Lett.*, 20, 204; 1973) have used both potassium-argon and fission track methods to date glass samples from the interior and rim of the crater and from areas up to 2 km away from the rim. The mean potassium-argon and fission track ages are 0.70 ± 0.08 and 0.74 ± 0.04 million years, respectively, giving a combined age of 0.73 ± 0.04 Myr. This compares with the fission track age of 0.72 ± 0.02 Myr for the longer-known glasses, obtained previously by Gentner *et al.* (*Geochim. cosmochim. Acta*, 33, 1075; 1969).

Gentner and his colleagues thus conclude that all the known Darwin glasses were produced at the time of the impact that formed Darwin Crater 0.73 Myr ago. But there may be more in this than simply a study of the relations between glass deposits. That the Darwin glasses occur geographically close to the Australasian tektites has been obvious for some time; and what Gentner *et al.* have now done is to show that the glasses and the tektites have the same age. This is apparently the first evidence obtained that an impact crater was formed at the time of the Australasian tektites. It seems hardly likely that this is a coincidence; and yet it is unlikely that an impact forming a crater as small as the Darwin Crater could be

responsible for the large Australasian tektite field. One reconciling conclusion is that the meteorite or comet fall (if such there was) leading to the formation of the Australasian tektites produced a number of craters, of which the Darwin Crater is but one. If so, a careful search in the area should reveal them in time.

No role yet for poly (A)

from our
Molecular Genetics Correspondent

ONE of the most intriguing questions in the area of messenger RNA production in eukaryotic cells is the role of the sequence of polyadenylic acid (poly (A)) which almost all the messengers seem to carry at their 3' end. A sequence of about 200 residues of adenylic acid is added, probably one base at a time, to the 3' end of the apparent mRNA precursor, heterogeneous nuclear RNA (Hn RNA), after or during its synthesis from chromatin. After cleavage of a 3' terminal sequence containing the poly (A), transport to the cytoplasm is succeeded by association with ribosomes for translation.

One speculation about the possible role of poly (A) is refuted by the results reported by Bard, Efron, Marcus and Perry in the February issue of *Cell* (1, 103; 1974). The idea that the poly (A) might be necessary solely for nucleocytoplasmic transport has previously been rendered less likely by observations that it is found in tumour viruses whose expression is confined solely to the cytoplasm and also in mitochondrial messengers where no transport is implicated. One inference which might be drawn from these results is that the poly (A) is implicated in some role in translation, perhaps controlling the stability of mRNA or its capacity to act as template for the ribosomes. Although the sequence of poly (A) on a messenger seems to shorten progressively with time passed in the cytoplasm, studies of mRNA turnover showed that this is not correlated with any increase with time in the probability of mRNA degradation.

The possible role of poly (A) in controlling translational capacity has therefore been examined by Bard *et al.*, using two types of experiment: in the first, they examined the abilities of messengers bearing different lengths of poly (A) to be translated within the mouse L cell; and in the second they compared the activities as templates *in vitro* of mRNAs either possessing or stripped of their poly (A) sequences.

Old and new mRNAs can be preferentially labelled in the L cell cytoplasm by labelling with ^{32}P , for 20 h but with ^3H -adenosine for only 1.75 h. When

polysomes are then extracted and analysed, the ^{32}P label identifies older messengers whereas the ^3H label is found in newly synthesised messengers. The new messengers possess a length of poly (A) of about 180 residues, but in the old messengers its length is much reduced and may be as small as 50 bases. Bard *et al.* found that there is no difference in the ratio of new to old mRNA in various polysomes fractions, implying that both classes of mRNA share the same translational capacity.

An alternative possibility, that overall translational efficiencies are different but that the same ratio of initiation to elongation is maintained, was excluded by experiments utilising temperature shock. This treatment disaggregates polysomes by preventing initiation of protein synthesis; ribosomes therefore run off their current messengers to release free messenger ribonucleoprotein. Lowering the temperature allows the polysomes to reform by utilising the released mRNP. After labelling old mRNA by incubating cells for 2 h with ^3H -uridine followed by a 21 h chase, and labelling new mRNA by incubation for 1 h with ^{14}C -uridine, Bard *et al.* found that reassembled polysomes display a ratio of new:old mRNA very close to that of the control. The capacity to initiate protein synthesis of both classes of messenger must therefore be virtually identical.

Because these experiments compare messengers possessing different lengths of poly (A), Bard *et al.* then turned to *in vitro* experiments to compare messengers with or completely without poly (A). By using a 3'-OH exoribonuclease to degrade the poly (A) sequence, and by then utilising only messengers which had retained their original size (to exclude those suffering other breaks), they isolated a messenger fraction identical to that usually extracted from L cells, but lacking poly (A). No difference could be found in the translational capacity of the deadenylated mRNA compared with the messengers possessing poly (A), using an *in vitro* system for synthesising proteins derived from wheat embryo.

Poly (A) therefore seems to lack any role in controlling the activity of messenger RNA in protein synthesis either *in vitro* or *in vivo*. The ubiquity of poly (A) in eukaryotic messengers (the only well established fraction lacking it is that coding for the histones) implies that it must have some important function. Previous experiments have excluded control of messenger lifetimes as its function, leaving it with no role apparent at the level of translation. Although preventing the addition of poly (A) halts the production of mRNA from HnRNA, the presence of poly (A) in messengers not derived from the nucleus suggests

that it must have some cytoplasmic function. No reconciliation of this paradox is evident at present: poly (A) remains a sequence in search of a function.

Inside the sickled red cell

from a Correspondent

CURRENT interest in sickle cell anaemia itself and in the behaviour of deoxy sickle cell haemoglobin was the subject of recent comment in these pages (see *Nature new Biol.*, 242, 33; 1973). This interest has been stimulated, partly by increased support in the United States for work on the clinical management of patients with sickle cell anaemia and tests of possible therapy, and partly by new insights into the aggregation of deoxy Hb-S from a variety of techniques, in particular electron microscopy and fibre type X-ray diffraction studies. There is now a considerable literature on the aggregation of deoxy Hb-S into an ordered phase, starting with the birefringence studies of Sherman in 1940, even before the recognition of Hb-S as a haemoglobin variant.

One of the latest additions to this literature is an optical study by Hofrichter, Hendrickson and Eaton (*Proc. natn. Acad. Sci. U.S.A.*, 70, 3604; 1973) on the orientation of deoxy Hb-S molecules within the long straight fibres which have been shown by electron microscopy to make up the ordered phase. The fibre model proposed by Finch and colleagues (*ibid.*, 70, 718; 1973) is a microtubule composed of stacked rings of six Hb-S molecules. Since each ring is rotated slightly, relative to the preceding ring, the structure can alternatively be envisaged as six intertwined helical filaments, each having about 48 Hb-S molecules per turn. Neither electron microscopy nor X-ray diffraction has as yet provided definite information on the orientation of the molecules within the fibre, or the role of the mutation sites (Glu A3(6) β \rightarrow Val) in the intermolecular contacts.

Eaton and his colleagues have made polarised absorption measurements on single sickled red cells and single crystals of deoxy Hb-S. The polarisation ratio of sickled cells gives a lower limit for that of an individual fibre, and taken in conjunction with the absorption properties of the haemoglobin molecule restricts the direction of the long molecular axis (z) to within 22° of the fibre axis. The highly anisotropic absorption ellipsoid of the haemoglobin molecule required for this work was calculated for the Soret band, since optical studies on haem protein single crystals by Eaton and colleagues had shown this haem chromophore transition to be nearly perfectly in-plane. The haemoglobin ellipsoid was

obtained by summing the squared projections of all the haem planes on to the form ellipsoid of the molecule, and this was then transformed into the crystallographic system.

After defining the limits of the orientation of the x axis, and using the Finch stacked-ring model for the molecular positions, with the requirement that at least one mutation ($\beta 6$) site is part of an intermolecular contact, the measured polarisation ratio for the Soret band requires that the true molecular dyad (y)

Diagram of one of the three classes of model for the orientation of molecules in the sickle cell fibre allowed by the optical results of Hofrichter *et al.* and by the additional constraint that at least one $\beta 6$ site is part of an intermolecular contact. If the maximum possible tilt of the x axis is used, the other $\beta 6$ residue of a molecule is in a position to make an interring contact.

axis passes through some part of an adjacent molecule in the same ring of six molecules. This range of orientation for the y axis turns out to be approximately perpendicular to those proposed in previous models.

The new information obtained from the optical studies allows three classes of model to be considered, which differ in respect of the possible dispositions of the $\beta 6$ sites. In all three models a $\beta 6$ residue could assist in stabilising intraring contacts. If the maximum possible tilt of the x axis is used, the other $\beta 6$ residue of a molecule is in a position to make an interring contact, though more extensive polarised absorption measurements will be required to establish this interesting possibility. In any case the absorption polarisation work, which is technically very impressive, has already provided new insights into the detailed structure of the deoxy Hb-S fibre and may suggest new approaches to the practical problem of inhibiting the aggregation process.

Not all at sea on the Channel

ON Thursday, January 31, a large contingent of French scientists converged

upon London to meet their English counterparts for two days of discussion on the geology of the English Channel. Although physical constraints required that the scientists meet in either London or Paris, metaphorically they met half way—a great deal of academic *entente* was evident throughout the proceedings. The meeting, jointly organised by the Royal Society and the Marine Studies Group of the Geological Society, was a great success. And it was not without its surprises: "I began", said one of the organisers, "by asking for volcanoes, and in the end I was given ice".

But despite the more surprising aspects, the meeting showed that a new understanding of Channel geology has emerged which will not only have important implications in future studies of the geology of north-western Europe, but which may well result in a considerable reappraisal of established theories concerning that area. This is largely due to the amount of detail about the basement geology which has been collected by the French scientists.

There is evidence to indicate that the region has had an important tectonic history, the effects of which have not been fully appreciated in the past. There have been two major phases in the history of the Channel, probably interspersed with many minor tectonic events. A. J. Smith (University College, London) believes that both phases are intimately associated with events in the history of the spreading Atlantic Ocean. Soon after the end of the Hercynian orogeny about 280 million years ago, the Atlantic began to open along a trend aligned with that of the Channel, and many of the primary structures of the Channel originated at this time. During the Early Cretaceous, probably about 130 m.y. ago, the second phase developed as the Bay of Biscay opened and the axial trend of the Atlantic changed to its present orientation.

Consideration of the present structure and geology of the Channel shows that its tectonic history must have had some influence on the geological evolution of northern France and southern Britain. The Channel can be divided into three areas on a structural basis: an area to the west of the Anglo-Norman Ridge; a central area between this ridge and the Bembridge-St Valery Line; and a third area to the east. It is as a result of studies of the central area that geologists have come to appreciate the importance of the Channel's tectonic history. Within this central region two east-west structures downturn beds to the south. Geophysical data indicate that the tectonic activity in the Channel has been largely restricted to vertical block movements of the basement (which to some extent are still continu-

ing), and the surface structures of the central area are probably reflections of the basement structure. But, the important fact is that the southernmost of these two structures joins the Bembridge-St Valery Line and becomes deflected onto the French coast. The deflected structure has become a very minor feature by the time it reaches the coast, but, significantly, it is in perfect alignment with major structural features which pass through northern France, and into the Massif Central. Furthermore, the northern extension of the Bembridge-St Valery Line passes into important structures in south Dorset.

The implication is that major structural features which have previously been interpreted without any consideration of the role of the events which are manifest in the Channel, will now have to be examined more closely. Are the Mendips really just part of the Hercynian Front, or do they in fact reflect the vertical movements of the basement rocks of this area? And was the Weald really folded into its present structure by epeirogenic movements during the Alpine orogeny; or is D. Curry (University College, London) correct in the reiteration of his old idea that the Hampshire, London and Somme basins did not form separately?

But despite the implications raised by these issues it was largely the well-received theory of G. A. Kellaway (Institute of Geological Sciences, London) and his colleagues which dominated the discussions. Early on in the meeting Smith had suggested that there may have been considerable volcanicity accompanying the first major tectonic phase, and that the lavas which accumulated may be responsible for the present isostatic balance which leaves the western area of the Channel as a basinal depression. Unfortunately none of the other speakers could provide proof for this attractive hypothesis, and so Kellaway, unable to provide a volcano, provided a glacier instead. He has managed to find an impressive amount of evidence, including boulder clay from the Slinden Pipes, to show that during the Anglian glacial advance the Channel was filled with glacial ice which moved eastwards from the edge of the continental shelf, and deposited the abundant erratics which today litter the coastline of southern England.

Kellaway also believes that the 'raised beaches' around the Sussex coastline are not raised beaches at all, but are marginal outwashed deposits. His theory could certainly provide an acceptable explanation for the previously mysterious buried channels and valleys and for the Hurd Deep, all of which may be the result of subglacial erosion.

Accuracy of tree-ring dating

from our Archaeology Correspondent

THE correction of the radiocarbon time scale by means of tree-ring dating has profoundly affected archaeological chronologies, and has important geophysical implications. Hitherto, the calibration has been based upon a single 7,400-year tree-ring sequence, established for the bristlecone pine by Ferguson. The production of an independent tree-ring sequence for the same species, extending back to 3535 bc (LaMarche and Harlan, *J. geophys. Res.*, 78, 8849; 1973) is thus of considerable importance. That it should differ by only two years from the original Ferguson sequence offers strong corroboration to both.

In both cases the trees examined are in the southern White Mountains of California. In the new study wood from a limited area on Campito Mountain, at elevations over 3380 m, was used; Ferguson's earlier study (page 237 in *Radiocarbon Variations and Absolute Chronology*, edit. by Olsson; Almquist and Wiksell, Stockholm, 1970) was based on wood from a lower elevation at Methuselah Walk, about 10 miles south of Campito Mountain. The Campito sequence is based on samples from 37 living trees, which take it back to ad 600, and woods from 70 dead trees were utilised to carry the sequence back to 3535 bc. There are three potential error sources in such a count. To the risk of extra intrannual rings is added that of locally absent rings. And, third,

there is the possibility of the mismatching of rings from one specimen to the next as the record is built up. LaMarche and Harlan conclude that false latewood and 'earlywood' bands can be recognised by their cell structure, so that the first problem is not difficult. They offer arguments to show that when there is a possibility of a few annual rings being uncounted in the chronology (that is of missing rings), "the error in the chronology from this source should only be of the order of one year". Cross-dating errors can be controlled by the recognition of characteristic frost damage rings, often shared by the different trees in a specific area in very cold years.

The importance of the work is that these considerations were put to the test by a detailed comparison of the Campito Mountain chronology with the Methuselah chronology. The cross dating is demonstrated objectively by means of cross-correlation analysis. This was first carried out using the dates originally assigned to the Campito chronology, and the coefficient obtained had negative or low values for part of the period. When the Campito dates were adjusted by insertion of two missing rings, the cross-correlation coefficients for the earlier period were positive and highly significant. The authors conclude: "The incidence of false rings that might erroneously increase the age is so small as to preclude explicit evaluation. The only important potential source of error seems to be locally absent rings. On the basis of the close agreement of the estimated number of rings absent from

the Campito chronology with the observed discrepancy between the Campito and Methuselah chronologies, it is highly probable that the absolute error of the Methuselah chronology at 3435 bc is, in fact, zero".

This conclusion is of fundamental interest to archaeologists and others who seek to use the dendrochronological calibration of radiocarbon, because hitherto this has been based principally on the Methuselah sequence. Although the accuracy of this sequence has not seriously been questioned, independent corroboration was desirable. Sceptics could yet argue that sequences obtained from trees of the same species, from locations only 10 miles apart, are not necessarily independent, but the results must strengthen the bristlecone pine sequence.

They cannot help, however, with two other problems of the calibration. In the first place there is the possibility that as a result of the diffusion of recent tree sap across older tree rings, the radiocarbon determination obtained from a given ring may yield a date substantially later than that of the ring's formation (Berger, *Phil. Trans. R. Soc. A*, 269, 33; 1970). And, second, the atmospheric concentration of radiocarbon in southern California may not always have been the same as, for instance, in Europe. These two problems can only be resolved by tests outside California. The long tree-ring sequence (mainly of oak) at present being established in Belfast may ultimately answer both questions. Meanwhile, comparison of radiocarbon dates obtained from dendrochronologically-dated bristlecone pine samples with radiocarbon dates obtained from archaeologically and historically dated samples from ancient Egypt at least produces no conflict. But the errors associated both with the radiocarbon determinations and with the Egyptian archaeological contexts are so large that this comparison is far from conclusive.

A problem related to these is that of the shape of the curve which relates calendar and radiocarbon dates. The version originally prepared by Suess had many kinks (page 303 in *Radiocarbon Variations and Absolute Chronology*). Other laboratories, notably at the University Museum in Philadelphia and the University of Arizona, have used smoothing procedures to give a more convenient curve, although as Burleigh has pointed out (*Antiquity*, 47, 309; 1973) there is at present no sound reason for eliminating the kinks.

This question of the precise shape of the curve is, however, secondary: the primary problem is the general and worldwide validity of the data upon which it is based. The new Campito sequence serves to confirm one of its

Standing snags of bristlecone pine on Sheep Mountain in the Campito Mountains of California. These trees have been

dead for more than 300 years. (Photo: Laboratory of Tree-ring Research, University of Arizona.)

sustaining arguments, and is thus a first step towards the validation of the calibration as a whole.

Pion capture reveals alpha clusters

from our Nuclear Theory Correspondent

WHEN a negative pion comes to rest it is captured by a nucleus and gives it all its rest energy. Since energy and momentum must be conserved in the capture process the pion cannot be captured by a single nucleon but must interact with several nucleons at once, so a detailed study of the particles emitted provides information on nucleon correlations in the nucleus.

One of the most likely forms of nucleon correlation is their tendency, especially in light nuclei, to form α clusters, and a recent experiment by Lewis, Ullrich, Engelhardt and Boschitz (*Phys. Lett.*, **47B**, 339; 1973) on the capture of negative pions by ^{16}O provides new evidence of the presence of these clusters in nuclei.

They looked at the γ -ray spectrum emitted by a ^{16}O target irradiated with slow pions and found a strong peak due to the 4.44 MeV γ -ray from the decay of the first 2^+ excited state of ^{12}C . It is thus natural to suppose that the pion capture has broken the ^{16}O into an α particle and an excited ^{12}C nucleus, and indeed it is known that this mode of breaking up is about six times more likely than the corresponding process leaving ^{12}C in its ground state.

Since the α particle has a momentum distribution relative to the ^{12}C in the original oxygen nucleus, the recoiling carbon nuclei have the same distribution, superposed on the recoil momentum determined by the rest mass of the pion. This momentum distribution produces a Doppler broadening of the shape of the γ -ray line, and measurement of this broadening gives the momentum distribution of the α particles.

This momentum distribution can also be calculated from a simple harmonic oscillator model, thus providing a check on the interpretation of the data. In such a model, the momentum distribution of a particle moving with angular momentum L with respect to the centre-of-mass of the harmonic oscillator potential has the form $P(K) \propto K^{2L} \exp(-K^2/2Q_0^2)$, and fits to the data given $Q_0 = 75 \pm 5 \text{ MeV/c}$. This may be compared with analyses of the $^{16}\text{O}(p, \alpha)$ knockout reaction that give $Q_0 \approx 75 \text{ MeV/c}$. The values of Q_0 and Q_2 are expected to be similar, so this is an indication of the consistency of the two analyses.

This experiment essentially gives the distribution of the sum of the momenta

of the four nucleons emitted when pions are captured by ^{16}O . These four nucleons are most probably combined to form an α particle because the alternative interpretation of absorption on a deuteron followed by evaporation of two nucleons would give the characteristic γ -rays from the decay of ^{12}B ; and these are not observed. Other possible origins of the observed γ -rays were excluded by repeating the experiment with different targets.

It is thus very reasonable to interpret these observations by the α particle absorption model and this gives further support to the idea that α clusters are present in nuclei. Similar results have been obtained for other nuclei besides oxygen.

Population energetics of kangaroo rats

from our Animal Ecology Correspondent

It has been suggested that because terrestrial herbivores have low efficiencies of consumption of net primary production (NPP), their populations generally are not limited by food (Slobodkin *et al.*, *Am. Nat.*, **101**, 109; 1966; Wiegert and Owen, *J. theor. Biol.*, **30**, 69; 1971). Most species of small mammals from the temperate biomes consume between 0.1% and 1.0% of the NPP annually. When this amount is expressed in terms of available productivity (AP)—that is, ignoring inedible parts of the plant—the values range from 0.1% to 4.0%, with a few exceptions (Chew and Chew, *Ecol. Monogr.*, **40**, 1; 1970; Wiegert and Evans, in *Secondary Productivity in Terrestrial Ecosystems* (edit. by K. Petrusewicz) 499, *Polish Academy of Science*, Warsaw, 1967; Grodzinski *et al.*, *Acta Theriol.*, **11**, 419; 1966). Sohlt has now published some interesting data on the impact of a population of the kangaroo rat (*Dipodomys merriami*) on the Mojave desert and shows that the rats take 6.9% of the NPP and 10.7% of the AP annually (*Ecol. Monogr.*, **43**, 357; 1973). The study offers some thoughts on why population densities of desert rodents are as high as they are.

Sohlt estimated population density by recapture trapping and the Lincoln Index. During the year of study the density averaged 16.2 rats ha^{-1} , a high figure for a species living in conditions where the NPP is just 1,400 megacal $\text{ha}^{-1} \text{yr}^{-1}$. (In temperate zones the NPP is between 20,000 and 30,000 megacal $\text{ha}^{-1} \text{yr}^{-1}$.) Sohlt measured resting energy expenditure, the energy cost of activity, the energy expense of growth, assimilation efficiency and calculated the total energy flow (E) through the population to be 85.5 megacal $\text{ha}^{-1} \text{yr}^{-1}$.

From his studies on growth and reproduction he deduced that the secondary productivity (P) of the population was 0.7 megacal $\text{ha}^{-1} \text{yr}^{-1}$, or 0.8% of the total energy flow. This is somewhat lower than the P/E ratio for other rodents which fluctuates between 1.2 and 3.0%. This suggests that kangaroo rats are not adapted for utilisation of as high a proportion of their total energy flow for secondary productivity as are non-desert species. Perhaps this adaptation is prudential in an environment where the amount of food production is unpredictable.

Although several species of plants were available to the rodents, they showed a strong preference for the annual storksbill *Erodium cicutarium*. Seeds formed the major item in the diet, but leaves were consumed during the winter. Laboratory studies showed the assimilation efficiency (AE) to be 0.87. Assuming this, the amount of food that had to be consumed such that E/AE equaled 85.5 megacal $\text{ha}^{-1} \text{yr}^{-1}$ was calculated to be 97.8 megacal $\text{ha}^{-1} \text{yr}^{-1}$. A little more than 1.0 megacal was supplied by arthropods; most of the rest by *Erodium*.

Further field studies revealed that, in order to obtain this calorific input chiefly from one species of plant, the rats consumed, incredibly, more than 95% of the *Erodium* seed production and more than 90% of the total *Erodium* production. The population thus exerted a massive effect on the energy turnover of this one species, although at 6.9% of the total NPP it had little effect on the vegetation as a whole. Its impact on the survival chances of this species population would be immense if the remaining 5% of the seeds are insufficient to support as great a plant population in the succeeding year. It is a pity that the study was not continued to ascertain what were the population levels of rat and storksbill during the following year. Populations of desert annuals are limited by rainfall so that desert rodents are unlikely to exert an important controlling effect. If rainfall was not limiting, the rodents would likely consume *Erodium* until it became scarce to find and in that way actually limit its population.

Sohlt's study shows that this population of *Dipodomys* lived dangerously on the brink of overexploiting its food resources. Wiegert and Owen suggested that low consumption of plants avoided long term oscillations of the plant populations. In deserts, where extremes of environmental factors make oscillations unavoidable, the evolution of such a damper would prove ineffective. Thus there is no disadvantage to a population of rodents consuming more than 95% of its major food source.

Glassy state good for lasers?

from our Solid State Physics Correspondent

LASER beams are often of such high intensity that the electric component of the electromagnetic wave reaches the level of the breakdown field for the medium through which it is travelling. In solids, local fractures and other damage are seen at a level of about 10^8 V m⁻¹ and in gases, plasma discharges are formed. The instantaneous field at which this takes place in solids is called the intrinsic optical damage field (the word 'intrinsic' is necessary because in solids there are other damage phenomena which are not intrinsic to the material and which are apparently caused by increased energy deposition in small imperfections in the transparent materials; these effects may occur at much lower light intensities than the electrical breakdown).

The intrinsic breakdown is interesting both from the fundamental and from the practical point of view. Electron avalanching is almost certainly the mechanism by which damage occurs and the processes by which hot electrons impart energy to a solid lattice is of great interest at present. Also, in the bid to make more and more powerful lasers, materials with the highest possible tolerance to the extremely high frequency electric fields present in the light pulse have to be found or fashioned; of special interest, of course, are the optically transparent glasses, mainly amorphous compounds with a wide band gap such as that possessed by many oxides. Here, the question of electron transport in a disordered lattice presents a double problem; first, because the theory of high field transport in any material with a wide band gap is not yet well developed and, second, because the theory of carrier scattering in disordered systems is more complex than that in crystalline lattices and is also in an embryonic state; some courageous attempts at predicting breakdown from data on lattice vibrational modes in an amorphous dielectric have, however, been made, with fair success (Lynch, *J. appl. Phys.*, **43**, 3274; 1972).

Thus the need for utilitarian data on the behaviour of glass optical elements in laser systems leads into a distinctly challenging area of research and leaves one to sink or swim, and perhaps to grasp at straws of data as they come past. Such a straw, perhaps, is a first report of a comparison of intrinsic damage fields in some glasses, some polycrystalline solids and some comparable single-crystal materials by Fradin and Bass, of Raytheon Research and the University of Southern California, re-

spectively (*Appl. Phys. Lett.*, **23**, 604; 1973).

The comparisons are between quartz and fused silica, polycrystalline and single-crystal potassium chloride and a germanate glass and its crystalline form. First, the fused silica did not show breakdown until a light intensity of 108 GW cm⁻² was reached, five times that at which crystalline quartz broke down. This factor of five in intensity corresponds to a factor of 2.2 in the relative damage fields. By contrast, polycrystalline potassium chloride broke down at about the same intensity as its single-crystal form (about 8 GW cm⁻²). Thus, both types of silica seem to be very good laser materials but, what is more, a large improvement seems to be gained by virtue of the microscopic disorder of the amorphous form. The disorder in this material is on the scale of a few lattice constants, taking the form of a dispersion of bond angles in an otherwise continuous and compositionally ordered network. The polycrystalline potassium chloride, of course, is disordered but is made up of crystallites which are many hundreds of lattice constants in size. Thus, grain boundaries do not seem to interfere with the progress of the gross damage effects (fractures and so on), which are the indicators of when the

intrinsic damage fields are reached, but microscopic disorder apparently damps the breakdown effect quite drastically.

Although this is only a straw in the wind, a set of data for only one amorphous/crystalline pair, it is tempting to grasp at it and say, as the authors do, that the disordered network is more efficient at extracting energy from the electrons before they reach the energy necessary for impact ionisation: that is, it is more difficult to heat the electron distribution in the disordered material. This is, however, equivalent to saying that the electron mobility in amorphous silica at high fields is considerably lower than that for the crystalline form; this is unlikely, since Hughes has found that, for fields up to 10^7 V m⁻¹ (though impurity content caused some variation) the electron mobility and lifetime in synthetic fused silica was generally higher than for pure crystalline quartz. (See, for example, *Nature*, **246**, 190; 1973). Nevertheless, the study of high field breakdown in solids induced by a laser, when carried further, may well prove quite a versatile and useful method for investigating the transfer of energy from hot electrons to their solid host medium, with unique possibilities for the localisation and shortening of duration of the accelerating fields.

Singing muscles in a katydid

from our
Insect Physiology Correspondent

INSECTS are commonly regarded as cold blooded, or poikilothermic—their temperature agreeing with that of the environment. But it was well known to Newport, writing in Todd's *Cyclopaedia* in 1838, that the honeybee without visibly moving increases its body temperature well above that of its surroundings; and it is now known that this change is accompanied by action potentials in the thoracic muscles without vibration. It has been known since Girard in the middle of the last century that hawk moths increase their thoracic temperature by as much as 10° C by vibrating their wings. Such a rise in temperature increases the efficiency and frequency of wing muscle contraction. Recourse was had to this effect in trying to explain the very high rates of contraction and relaxation in the flight muscles of insects, which far exceed those of vertebrates. The rate of wing beat in the humming bird is 30–50 cycles per second: the blowfly will beat its wings at 150 cycles per second, a rate too rapid to be explained by a rise in temperature alone.

It was suggested that these wing muscles were operating in a state of incomplete tetanus. But the explanation

was ultimately found by Pringle who showed that these high rates of oscillation are myogenic: the rapid contraction of one set of muscles is induced by the stretching brought about by their antagonists; whereas shortening of the muscles leads to a rapid relaxation of tension. This same mechanism can explain the high rate of vibration in the timbal muscles of cicadas which may go up to 4,500 Hz.

It has now been shown by Josephson (*J. exp. Biol.*, **59**, 781; 1973) that in the singing katydids *Neoconocephalus* and *Eoconocephalus*, relatively high rates of sound pulses, rising to about 200 Hz, generated by rubbing the wings together, are controlled by synchronous, or neurogenic, muscles in which each contraction is initiated by a nerve impulse. The high rates of contraction are dependent on two factors: a rise in temperature to about 36° C (12° C above ambient temperature) in the thoracic muscles, and a consequent persistence of an unfused tetanus in the muscles at rates of 160 Hz or more.

This mechanism is expensive in energy, for each muscle must contract while its antagonist is still contracting, and the songs may continue for several hours on end. But the heat produced is necessary to maintain the required temperature; and the author suggests that the mechanism may have evolved as the result of sexual selection—the females opting for the males with the highest pulse frequencies in their song.

Stratigraphic record of Early Eocene *Hyopsodus* and the geometry of mammalian phylogeny

Philip D. Gingerich

Peabody Museum of Natural History and Department of Geology and Geophysics, Yale University, New Haven, Connecticut 06520

Eocene strata in Wyoming spanning a period of 5 million years record a branching phylogeny which exhibits gradual phyletic evolution, overall size increase with iterative evolution of small species and character divergence following the origin of each new lineage.

THE gradual nature of evolutionary change was a central tenet in Darwin's *Origin of Species*¹. Darwin acknowledged that new forms of life appear suddenly in the fossil record and attributed this to gaps in the record. He stated that the stratigraphical column was probably not sufficiently complete to record in ancient lineages the continuous gradual change through natural selection that he and others had observed in domestic animals under artificial selection. The phylogeny of the condylarth *Hyopsodus* presented in this report is the first detailed record of mammalian evolution at the species level. The record is based on numerous superposed stratigraphical levels within one restricted geographical area of one geological formation: it provides new palaeontological evidence of Darwinian gradualism in evolution.

Phylogeny of *Hyopsodus*

Condylarths are archaic ungulates which are important because they were abundant in the early Tertiary and because the group includes the ancestors of the living Artiodactyla and Perissodactyla. During the past ten years, Yale expeditions have made large collections of fossil mammals from approximately 400 localities in the Early Eocene Willwood Formation^{2,3} of the Big Horn Basin in northwestern Wyoming. *Hyopsodus* is the most common mammal in these collections, being represented by approximately 4,000 jaw fragments containing two or more teeth. Morphologically, *Hyopsodus* had a long body with relatively short limbs (see inset in Fig. 1), suggesting a fossorial habit. In 1965 measurement of a stratigraphical section 1,690 feet (515 m) thick was completed by G. Meyer and L. Radinsky in the Antelope Creek-Elk Creek-Fifteen Mile Creek drainage area which covers a geographical area of approximately 20 km by 60 km, all of which is badlands with little or no cover of vegetation. The measured section spans most of Early Eocene time, a period of approximately 5 m.y.⁴.

The original stratigraphical section included forty-five localities yielding specimens of *Hyopsodus*, and the nearly horizontal attitude of strata in this area permitted interpolation into the original section of an additional ninety localities yielding *Hyopsodus* discovered since 1965. The stratigraphical position of each of these localities was determined to the nearest 20 feet (6.1 m), then the length and width of all lower first molars of *Hyopsodus* were measured and the log of the product of the measurements was computed for each successive interval. The product of length multiplied by width of M_1 is the best dental measurement for characterising the size of closely related mammalian species, and it is in general the best discriminant of closely related species occurring together in any one stratigraphical level⁵. Sympatric species of the same genus living today can only rarely be diagnosed by morpho-

logical differences in their cheek teeth, though the species usually differ significantly in size. Similarly, for the *Hyopsodus* from a given stratigraphical level, size is the only characteristic of the molars which permits species diagnosis.

Size is plotted against stratigraphical position in Fig. 1 for all specimens from the study area containing M_1 (a total of 928). In this plot a number of lineages are apparent, the best defined being those labelled *Hyopsodus latidens*-*H. minor*, *H. lysitensis* and *H. powellianus*. The range of variation of the sample of ninety-two *H. lysitensis* from level 1,360 is typical of living species, and undoubtedly closely approaches the maximum variation in size to be expected in any sample of a species of *Hyopsodus*. Samples at levels 440, 600, 660, and 1,240 have ranges of variation exceeding that expected of one species and the samples have tentatively been divided to indicate this, though they are not clearly bimodal.

The dashed lines in Fig. 1 indicate the limits of variation of each of the well defined lineages, and in addition show the most probable relationships of *H. simplex*, *H. wortmani*, *H. mentalis*, and *H. walcottianus* to the better represented species. It is apparent from the figure that the relatively small species *H. loomisi* gave rise in early Gray Bull time to two species *H. simplex* and *H. sp. A*. *Hyopsodus sp. A* gave rise in late Gray Bull time to *H. latidens* and *H. miticulus*. In the Lysite, *H. miticulus* gave rise to *H. lysitensis* and *H. powellianus*. *H. powellianus* apparently gave rise to *H. mentalis* and *H. walcottianus* at the beginning of Lost Cabin time. *H. minor* and *H. wortmani* are Lysite and Lost Cabin descendants of *H. latidens* and *H. lysitensis*, respectively.

The coexistence of three species of *Hyopsodus* in late Gray Bull, Lysite and Lost Cabin times is confirmed, although the relationships of each of these species are fundamentally different than has been proposed by recent authors. Gazin⁶ and Guthrie⁷, who grouped all specimens into either a lower Gray Bull, an upper Gray Bull, a Lysite or a Lost Cabin sample, proposed (using the species names of Fig. 1) that *H. loomisi* gave rise to a small, a medium and a large species, each of which then continued relatively unchanged through upper Gray Bull, Lysite and Lost Cabin strata. In other words they advocated a small lineage *H. simplex*-*H. minor*-*H. wortmani*, a lineage of medium-sized species *H. latidens*-*H. lysitensis*-*H. mentalis*, and a lineage of large species *H. miticulus*-*H. powellianus*-*H. walcottianus*. Division of the lower Eocene strata into forty-seven levels, instead of the four used by Guthrie and Gazin, shows that only the last group is a true evolutionary lineage. Whereas Gazin and Guthrie portray three lineages, each appearing suddenly and continuing almost unchanged through the remainder of the Early Eocene, it is clear from Fig. 1 that each new species evolved gradually from its parent species. Indeed, no species appeared abruptly, a fact which accords well with Darwin's view.

Each *Hyopsodus* lineage underwent gradual but significant size change. In the *H. latidens*-*H. minor* and *H. lysitensis*-*H. wortmani* lineages this change was sufficient to justify dividing each lineage into two time-successive phyletic species. Plotting the size data on a log scale makes the variability of samples of large and small species comparable but tends to

Fig. 1 Stratigraphical record and phylogeny of Early Eocene species of *Hyopsodus*. Abscissa is the \log_{10} of the length (mm) multiplied by width (mm) of the first lower molar. Ordinate is height (feet) above base of Willwood Formation, which includes Gray Bull, Lysite and Lost Cabin faunal zones. Sampling interval is 20 feet (6.1 m); average duration of one 20 foot interval is about 60,000 yr. Vertical slash is mean, heavy bar is standard error of mean, light bar is observed range, small numerals indicate sample size, and filled circles represent single specimens. Open circles and dashed lines at top of figure are means²⁸ and expected ranges for Lost Cabin species from the Wind River Basin which are poorly represented in the Willwood section. Inset, flesh restoration of *Hyopsodus* from Gazin⁶.

obscure the great overall increase in size in this radiation. The *Hyopsodus* radiation clearly conforms to Cope's rule, which states that there is a tendency for animal groups to evolve toward larger physical size (or from small size⁸). Of the eleven *Hyopsodus* species represented, however, six species became smaller and only five larger during the course of their evolution, indicating that Cope's rule does not deterministically describe evolution at the species level.

Iterative evolution, whereby a number of distinctive forms evolve repeatedly from one stem lineage, has been documented in the evolution of lobsters⁹ and in the evolution of pygidium morphology in Cambrian trilobites¹⁰. The same phenomenon is apparent in Fig. 1, where four small species *Hyopsodus simplex*, *H. minor*, *H. wortmani* and *H. mentalis* were derived successively and independently from the larger stem lineage *H. loomisi*—*H. sp. A*—*H. miticulus*—*H. powellianus*—*H. walcottianus*.

Palaeontological evidence such as that presented in Fig. 1 has occasionally been used to support the thesis that species arise sympatrically. In this case, as in earlier cases¹¹, allopatric speciation with subsequent migration may explain the fossil record equally well. It is clear from Fig. 1 that speciation must have preceded size divergence. Presumably speciation in *Hyopsodus* involved the evolution allopatrically of significant hybrid inviability between two populations, followed in sympatry by gradual size divergence to decrease interspecific competition¹².

The length of time observed before two lineages became clearly distinct in size is somewhat surprising. In the best documented case, *H. lysitensis* and *H. powellianus* seem to have required about 40 feet (12.2 m) of section, or on the order of 100,000 yr to become clearly differentiated. This slow, gradual divergence differs considerably from the expected rapid rate of displacement if resource competition between species was the

only controlling factor¹³. Species of *Hyopsodus* are the most common fossil mammals found in the Lower Eocene of North America. They presumably lived in populations of large size, and the slow rate of genetic change in large populations¹⁴ may have retarded the speed with which size displacement could be accomplished.

Geometry of mammalian phylogeny

A persistent gap in the palaeontological evidence for evolution has been the apparent absence in the fossil record of intermediate forms linking two species unequivocally to a common ancestor. Palaeontologists have generally reacted to this absence of intermediate forms by continued search for more complete stratigraphical sections. Recently a new 'punctuated equilibrium' model of animal phylogeny has been advanced^{15,16}, which explains the gaps in the fossil record as a natural result of allopatric speciation. According to this model, new species arise as peripheral isolates of a central population and the isolate, being small, has virtually no chance of being preserved in the fossil record. A successful isolate may replace the central population in a relatively short period of time—instantaneously considering the length of geological time. The postulated pattern of phylogeny resulting from this model includes long periods of time without significant morphological change in a lineage. Rarely this morphological equilibrium is punctuated by a rapid speciation event. The net result, according to the punctuated equilibrium model, is a fossil record of isolated static species without intermediate linking fossil populations.

The punctuated equilibrium model can be tested only by a relatively complete, stratigraphically controlled fossil record such as that of *Hyopsodus* already described. The phylogeny of *Hyopsodus* appeared^{6,7} to conform to the punctuated equi-

brum model and for this reason it was chosen to test the model.

Figure 1 shows clearly that when a large number of stratigraphical levels were studied within the Willwood Formation, the resulting phylogeny of *Hyopsodus* exhibited neither long periods of morphological equilibrium, nor rapid speciation events. Probably the chief reason why interspecies transitions are rare in the fossil record is, as Darwin proposed, because of the incomplete nature of most stratigraphical sections. Local stratigraphical successions that seem to be nearly complete, such as the Willwood Formation section, have still only rarely been studied in detail. In addition to the multi-lineage radiation described in this report, a number of other examples in the literature exhibit phyletic gradualism in single lineages of invertebrates¹⁷⁻²⁰ (although details of these studies have been challenged, for numerous characters gradual evolution remains the most parsimonious interpretation, given the fossil record in each case) and vertebrates²¹⁻²⁵. The punctuated equilibrium model remains to be substantiated by a detailed stratigraphical study within a single geological formation.

The fossil record of *Hyopsodus*, when studied in detail, seems to justify Darwin's view that species evolved gradually. Study of other characters in other phylogenies of species with a good fossil record is needed to determine the extent to which population size, character variability²⁶ and other factors affect the rate of evolutionary divergence following speciation.

The stratigraphical record of human evolution unfortunately still includes many gaps; study of the available evidence in a stratigraphic context²⁷, however, suggests that hominid phylogeny conforms to the pattern of gradual-character divergence exhibited here by *Hyopsodus*.

The *Hyopsodus* specimens on which this report is based were collected by Yale expeditions directed by Professor E. L. Simons; and I thank him for access to this collection. I also thank P. Dodson, N. Eldredge, J. Ostrom, D. Pilbeam,

E. Simons, F. Simons, G. Meyer, T. Bown for discussion; M. McKenna, D. Savage for comparative specimens; M. Egan for assistance with Fig. 1. Financial assistance provided by a Shadle Fellowship of the American Society of Mammalogists is gratefully acknowledged.

Photoreactivating enzyme from human leukocytes

Betsy M. Sutherland

Department of Molecular Biology and Biochemistry, University of California, Irvine, California 92664

A photoreactivating enzyme has been found in human leukocytes. The specificity of the enzyme for cyclobutyl pyrimidine dimers in DNA may allow direct evaluation of the role of dimers in ultraviolet-induced carcinogenesis in man.

PHOTOREACTIVATION is the specific repair of ultraviolet (220-300 nm)-induced cyclobutyl pyrimidine dimers in DNA¹. The reaction is carried out by the photoreactivating enzyme, which requires light in the range 300-500 nm for its activity^{2,3}. The specificity of the enzyme for pyrimidine dimers enables its use as a diagnostic tool: if ultraviolet-induced biological damage is photoreactivable, pyrimidine dimers are probably a major cause of the damage⁴. This approach has been used to show that dimers are largely responsible for ultraviolet-induced death and mutation in prokaryotes and simple eukaryotes⁵⁻⁷.

Ultraviolet light produces skin cancer in humans, which in the extreme case of xeroderma pigmentosum leads to death⁸. Consequently, it is important to evaluate directly the role of dimers in the induction of such cancers in man. The apparent lack of the photoreactivating enzyme in placental

mammals^{4,9} has prevented direct evaluation of the role of dimers in human carcinogenesis although studies with model systems are in progress¹⁰.

I show here that human cells do have a photoreactivating enzyme. I have purified the enzyme to apparent homogeneity and have studied some of its physicochemical properties.

Radioactive DNAs were prepared as previously described¹¹. The specific activity of the ³²P-labelled T7 DNA was 397 c.p.m. pmol⁻¹ and that of the ³H-thymidine-labelled T7 DNA was 12.5 c.p.m. pmol⁻¹. Pyrimidine dimers were produced by exposure to 254 nm radiation; dimer content of ³H-thymidine-labelled DNA was determined by formic acid hydrolysis, chromatography in *n*-butanol: acetic acid: H₂O (40:6:15), elution and counting of dimer-containing and monomer-containing regions of the chromatogram in a scintillation counter¹². For the ³²P-DNA, the dimer content was determined by (1) digestion of the DNA with DNase I, venom phosphodiesterase and alkaline phosphatase to a mixture of inorganic phosphate, mononucleosides and dimer-containing ³²P-labelled oligonucleotides; (2) adsorption of the labelled oligonucleotides to Norit, and (3) counting in a planchet counter¹¹.

TABLE 1 Summary of purification procedures

Procedure	Fraction	Volume (ml)	Protein (mg ml ⁻¹)	Units (pmol h ⁻¹)	Specific activity (pmol mg ⁻¹ h ⁻¹)
Cell extract	1	2.0	82	400	2.44
Ammonium sulphate pellet	2	1.0	6.2	256	41.4
Isoelectric focusing pool	3	1.0	0.015	95	6,350.0

Photoreactivating enzyme activity was assayed by adding cell extract or purified enzyme to 0.2 ml 0.02 M potassium phosphate buffer, pH 7.2, containing 0.1 mM dithiothreitol, 0.1 mM EDTA and 30-100 pmol of ultraviolet irradiated, ³²P-labelled T7 DNA. For each determination one assay tube was placed in the dark and another was exposed to photoreactivating light from a General Electric 150-W spot lamp. The dimer content of the samples was then determined as described above. Photoreactivating activity is the difference in dimer content of the light and dark samples; units of photoreactivation are pmol⁻¹ mg⁻¹ h⁻¹. Protein concentrations were determined by the Lowry method¹⁸, using bovine serum albumin as the protein standard.

The enzyme

Plasmagel (Bellon Labs) (4 ml) was added to 12 ml of freshly drawn human peripheral blood treated with 170 U of heparin. The suspension was mixed gently and allowed to settle 45 min at 37°C. The supernatant suspension, from which most of the erythrocytes had settled, was centrifuged at 2,000 r.p.m. in the SS-34 rotor of the Sorvall RCB-2. The cells were washed three times by gentle resuspension in 2 mM potassium phosphate buffer, pH 7.2, containing 0.15 M NaCl and centrifugation as before. Washing removed serum proteins and proteins added with the Plasmagel. The cells

TABLE 2 Characterisation of the photoreactivating enzyme activity

Enzyme	Ultraviolet exposure to ³² P-labelled T7 DNA (erg mm ⁻²)	Photo-reactivating light exposure (min)	Photo-reactivating enzyme activity (pmol h ⁻¹)
Fraction 3	3,000	0	0.1
Fraction 3	3,000	30	10.3
Fraction 3, trypsin treated, 34°C 5 min	3,000	30	6.53
Fraction 3	0	30	0.12
None	3,000	30	0.02

Fig. 1 Photoreactivation of dimers in ³H-thymidine-labelled DNA. Fraction 2 enzyme was added to 155 nmol of dimer-containing ³H-thymidine-labelled DNA in a standard assay mixture. After 5 min incubation at 37°C in the dark, one sample (○) was kept in the dark while the others (Δ) were exposed to 30 min of photoreactivating light. The dimer content of the samples was determined by the method of Setlow *et al.*¹².

were suspended in 2 ml of buffer E (10 mM Tris, pH 7.0, 0.1 mM EDTA, 0.1 mM dithiothreitol) and sonicated for 45 s in a Kontes sonicator. The resulting solution was fraction 1. Solid ammonium sulphate (0.163 g ml⁻¹ of fraction 1) was added and the mixture was stirred gently for 15 min on ice. The solution was centrifuged for 15 min at 15,000 r.p.m. in the SE 12 rotor of the Sorvall. Less than 30% of the photoreactivating enzyme activity appeared in the pellet; to the supernatant was added 0.163 g (per ml of fraction 1) of ammonium sulphate; the mixture was stirred 15 min after all the ammonium sulphate had dissolved, and centrifuged in the SE12 rotor as before. All the enzyme activity appeared in the pellet, which was dissolved in 1 ml buffer E (fraction 2). Fraction 2 was layered into the middle of an isoelectric focusing gradient (110 ml) prepared as follows: the cathode was placed at the bottom of the column. The cathode solution contained 14 ml H₂O, 0.2g NaOH and 12g sucrose. Sample of 55 ml of a 110 ml linear density gradient (formed by mixing in a LKB gradient apparatus a solution of 47.8 ml glycerol, 5 μl 0.1 M EDTA, 5 μl 0.1 M dithiothreitol, 9.83 ml H₂O and 1.88 ml LKB pH 3.5-10 ampholine solution with a solution of 57.4 ml H₂O, 5 μl 0.1 M dithiothreitol and 0.625 ml of the ampholine solution) was layered into a 110 ml jacketed isoelectric focusing column maintained at 4°C by a Lauda circulator. Fraction 2 was layered onto the gradient solution, and the rest of the gradient solution was then added. The anode solution (0.1 ml phosphoric acid, 10 ml H₂O) was layered on top of the gradient. A voltage of 300 V was applied across the column for 72 h. Fractions (0.5 ml) were collected and assayed for photoreactivating enzyme activity. Although several small peaks of enzyme were detected at pH values greater than 5.4, most of the enzyme was located at pH 5.4. The peak fractions were combined to yield fraction 3. The purification procedure is summarised in Table 1.

As Table 2 shows, the purified enzyme requires ultraviolet-irradiated DNA and photoreactivating light for its activity. The enzyme preparation must be added to the DNA for the reaction to proceed. The most important property of the enzyme is its ability to monomerise pyrimidine dimers in DNA. Since the ³²P-DNA assay for photoreactivation is indirect, I tested the ability of the enzyme preparation to reverse dimers in ³H-thymidine-labelled DNA. In this case both dimers, TT and CT, and the monomer, T, can be isolated and measured directly. Figure 1 shows that in the presence of photoreactivating light the enzyme preparation causes dimers to disappear from the ³H-thymidine-labelled DNA. In the dark the dimer content decreases very little, if at all; thus

Fig. 2 Molecular weight determination. The elution position on a 27×1.1 cm column of Biogel P-100 in buffer E + 1.0M NaCl of protein standards (bacterial alkaline phosphatase (▲), horse haemoglobin (●), cytochrome c dimer (■) and trypsin (□) was determined. The elution position of the human photoreactivating enzyme (V) was used to estimate its molecular weight at 40,000.

the disappearance of dimers from DNA in the light is due to true monomerisation rather than excision. The demonstration of photoreactivation by the 32 P-DNA assay also indicates that excision did not occur, as this assay does not distinguish excised dimers (in short pieces of DNA) from those remaining in high-molecular-weight DNA¹¹.

Since several types of low molecular weight molecules sensitise monomerisation of dimers¹⁴⁻¹⁶, it was important to show that the species in this preparation responsible for dimer monomerisation has a protein component. Treatment of the enzyme with 10 mg trypsin for 1 and 5 min at 34° C decreased enzyme activity to 85 and 59% of its original value, respectively. In this time the treatment at 34° C without trypsin did not affect enzyme activity. It is thus likely that the molecule responsible for photoreactivation has a protein component.

The enzyme has an apparent molecular weight of 40,000 (Fig. 2). The isoelectric pH of the enzyme is 5.4, which agrees qualitatively with the rapid migration towards the anode of the enzyme on polyacrylamide gels carried out under non-denaturing conditions (see below).

As with the *E. coli* photoreactivating enzyme, the pH optimum of the human enzyme is 7.2. At pH values 8.1 and 6.8 the enzyme showed 29 and 49% of the activity exhibited at pH 7.2. However, the human enzyme is inhibited by high ionic strength and at $\mu = 0.18$, the optimum for the *E. coli* enzyme, the human enzyme has only 20% of the activity it has at $\mu = 0.05$.

The final enzyme preparation, fraction 3, yields one major protein band on electrophoresis under non-denaturing conditions (Fig. 3). That this band is photoreactivating enzyme was shown by slicing a gel into 0.5 cm lengths, eluting the protein by electrophoresis from the gel and assaying each fraction for photoreactivating enzyme activity. The major band of enzyme activity coincided with the major protein band on the gel. In addition, two smaller peaks of enzyme activity appeared in the regions 0-1 and 0.3-0.4 of the gel. Since fraction 3 enzyme is isolated from a narrow band of the isoelectric focusing column, it is unlikely that these smaller peaks represent multiple enzyme species; rather they are probably aggregates of the enzyme into dimer and higher multiples. Such aggregates have also appeared in glycerol gradients performed in conditions of low ionic strength.

Photoreactivation in mammalian cells

Although photoreactivation is found in all phyla and in many types of cells⁴, data on the presence of the photoreactivating enzyme in placental mammals have been contradictory¹⁷⁻²². The problems in interpreting these data are, (1) for positive results, to distinguish between true cases of enzymatic photoreactivation and effects due to photoprotection, and (2) for negative results, to differentiate true absence of the enzyme from inadequate exposure or insensitive assay procedures. Clearly photoreactivation is more difficult to demonstrate *in vivo* in mammalian cells than in other cells; whether this is due to the low cell content of the enzyme or to the inaccessibility of the DNA to the enzyme is not clear. Cook⁴ reported an example of the latter: cell cultures of the South American woolly possum (*Caluromys derbianus*) Tasmanian potoroo (*Potorus tridactylis*) and opossum (*Didelphis marsupialis*) (all marsupials) had detectable photoreactivating enzyme when assayed *in vitro* whereas *in vivo*, they required very long exposures (6 h) to photoreactivate 40% (potoroo) and 65% (woolly possum) of their dimers. But if inaccessibility of DNA had been the cause, Cook and McGrath⁹ should have detected enzyme activity in placental mammals *in vitro*. These are two possible explanations for their failure to do so. First, although they assayed various tissues, they did not test mammalian leukocytes, in spite of the high activity they found in toad leukocytes. Second, they may not have been able to detect the enzyme if it had been present. Unlike the yeast and *E. coli* enzymes, the human enzyme is inhibited at high ionic strength, and at

Fig. 3 Absorbance and photoreactivating activity profiles of fraction 3 enzyme. The 5% gels were prepared according to the method of Davis²³. Two gels were prepared: after electrophoresis, one was stained in Coomassie blue and, after destaining, was scanned in a Gilson spectrophotometer for determination of protein distribution. The other gel was sliced into 0.5 cm segments; the enzyme was eluted by electrophoresis and assayed for photoreactivating enzyme activity as usual. The peak at 0.81 is tracking dye.

the ionic strength used by Cook and McGrath (0.11) it would have been only 35% as active as under optimal conditions ($\mu = 0.05$).

Photoreactivation is of primary biological interest as an analytical tool. Since the photoreactivating enzyme acts specifically on cyclobutane-type pyrimidine dimers, true enzymatic photoreactivation of ultraviolet-induced biological effect indicates that pyrimidine dimers were the molecular alteration responsible for the damage. Such tests have shown that dimers are a primary cause of death and mutation in prokaryotic and eukaryotic cells⁵⁻⁷.

Since sunlight induces cancer in man, it is tempting to speculate that pyrimidine dimers are the molecular cause of such cancers. But so far, it has not been possible to test this hypothesis directly and model systems have been necessary: Hart and Setlow presented data indicating that ultraviolet-induced, potentially tumorigenic lesions in the fish *Poecilia formosa* can be photoreactivated¹⁰. But now it should be possible to select a human or other placental mammalian cell type and photoreactivation conditions optimal for the direct evaluation of the role of pyrimidine dimers in the induction of cancerous growth by ultraviolet light.

I thank Professor G. A. Granger and members of his laboratory, Dr R. Daynes, P. Runge, J. Kramer and T. Jeffes, for help in obtaining and advice on handling the leukocytes; Professors M. J. Chamberlin and J. C. Sutherland for helpful discussions, and R. Knauft for technical assistance. This work was supported by grants from the National Institute of Health and California Cancer Research Coordinating Committee.

Specialised transformation in *Escherichia coli* K12

Michio Oishi & Sharon D. Cosloy

The Public Health Research Institute of the City of New York, Inc., 455 First Avenue, New York, New York 10016

A specialised transformation system has been developed in E. coli K12 by using specialised transducing phage DNA as donor DNA. Transformation of a marker on a F' episome has also been achieved.

GENERALISED transformation for chromosomal markers in *Escherichia coli* K12 has been reported recently¹⁻⁴. These studies demonstrated two major factors in determining the transformability of *E. coli*: CaCl_2 treatment of the cell surface to allow permeation of DNA and an appropriate intracellular status of various DNases, especially the ATP-dependent (*recB-recC*) DNase⁵⁻⁸. In this, as in other bacterial generalised transformation systems, the chromosomal donor DNA which is used is heterogeneous with respect to molecular size and genetic information. A transformation system in which essentially all the donor DNA is homogeneous in its genetic composition and its molecular size would be advantageous for studying various aspects of transformation, especially for studying molecular mechanisms of recombination. DNA from specialised transducing *E. coli* phages seems to be the ideal source of transforming donor DNA for this purpose because of the well characterised DNA structure and the relative ease of obtaining a large quantity of pure DNA which is unique for a specific region of the chromosome.

We report here such specialised transformation of a recipient chromosomal as well as an episomal (*F'*) genetic marker. This was demonstrated by using donor DNA isolated from phages $\phi 80\text{pt}^{9,10}$ and λpt^{11} , which carry tryptophan genes, to transform a tryptophan-requiring strain to tryptophan prototrophy.

Isolation of transforming DNA from *E. coli* (Hfr C6) was described previously⁴. The phage DNA was isolated by a phenol procedure¹² after purifying the phages by CsCl density centrifugation. The DNA preparations were extensively dialysed against 1/10 SSC (15 mM NaCl — 1.5 mM Na-citrate), and were heated at 70° C for 10 min before use. Shearing of the DNA was carried out with a Sorvall Omni mixer. Transformation was performed as described previously⁴, except that the reaction was stopped by the addition of an equal volume of cold 50 mM sodium citrate. Bacterial and phage strains and all the mutant markers are described in Table 1. In the text only the relevant mutations of each strain will be indicated.

Specialised transformation

Tables 2 and 3 show typical results of experiments involving specialised transformation of a *trp* mutation (*trpB*) with $\phi 80\text{pt}$ (*trpA*⁺*B*⁺*C*⁺) and λpt (*trpA*⁺*B*⁺*C*⁺*D*⁺*E*⁺) DNA. The

** Original F' is described in ref. 14. Before transfer to M0640, the *trpB9579* mutation was introduced and the *lac* genes were deleted.

†† Constructed by mating with Hfr KL16-99.

‡‡ Isolated from phages released from a φ80pt(*trpA+B+C+*) lysogen of W3110 (*trpB9579*)¹³.

φ80pt (*trpA+B+C+*) used as donor DNA carries a part (*trpABC*) of the *trp* operon of the *E. coli* chromosome, in place of the *int-red* region of the φ80 genome. Therefore, the φ80pt is *int- red-* and *trpA+B+C+* (ref. 15). This *int- red-* condition of φ80pt eliminates the phage recombination systems which might have complicated studies of the host recombination system. For similar reasons, we have also used DNA from λpt(*trpA+B+C+D+E+*), a plaque-forming phage λ containing the entire *trp* operon of *E. coli* in place of at least the *int-red* region of the bacteriophage λ chromosome as in φ80pt. As Table 2 shows, when CaCl₂ treated cells of the multiauxotrophic transformable *E. coli* K12 strain (M0671 *recB21 recC22 sbcB15 trpB9579 leu-6 tonB*) were exposed to unshredded, intact DNA isolated from φ80pt(*trpA+B+C+*), considerable numbers of Trp⁺ transformants appeared on the selective plates, but no Leu⁺ transformants were detected. The same degree of specialised transformation for *trpB* was also observed with sheared φ80pt(*A+B+C+*) DNA which had an average molecular weight of 8×10^6 , approximately a quarter the size of a φ80 genome (31×10^6)¹⁶. Fig. 1 shows the profile of transforming activities of the sheared φ80pt DNA after sucrose gradient centrifugation, showing that the transforming activity observed with the sheared DNA is not due to transformation by any residual intact φ80pt DNA

TABLE 2 Transformation of the *trpB* mutation with φ80pt and λpt DNA

Source of DNA	No. of transformants	
	Trp ⁺	Leu ⁺
None	0	0
φ80pt (<i>trpA+B+C+</i>)	1,808	0
φ80pt (<i>trpA+B+C+</i>), sheared	1,814	2
λpt (<i>trpA+B+C+D+E+</i>)	1,158	0
λpt (<i>trpA+B+C+D+E+</i>), sheared	840	0
<i>E. coli</i> Hfr C6 (<i>trp+ leu+</i>), sheared	106	144

This transformation was performed as described previously⁴ with a slight modification (see text) using M0671 as the recipient cells. The concentrations of the DNA used were 5 μg per 0.5 ml for φpt and λpt DNA and 10 μg per 0.5 ml for *E. coli* DNA. The average molecular weight of sheared DNA was 8.5×10^6 , 8.9×10^6 and 10×10^6 for φ80pt, λpt and *E. coli* DNA, respectively. The number of transformants is presented as the sum of the Trp⁺ or Leu⁺ colonies produced with a total of 2.2×10^7 viable recipient cells.

molecules. A slight shift of the activity from the peak of the absorbance profile of the quarter molecules toward the higher molecular weight side is probably due to the unique effect of the molecular weight of donor DNA in the transformation of *E. coli*; maximum transforming activity was

Fig. 1 Sucrose gradient centrifugation of sheared φ80pt DNA. Fifty μg of sheared φ80pt(*A+B+C+*) and ³H-φ80 DNA (0.05 μg, reference marker) in 0.5 ml of 1/10 SSC were applied to an 11.5 ml gradient of 5–20% sucrose in a buffer of 20 mM Tris-HCl, pH 7.6, 1 M NaCl and 1 mM EDTA. The centrifugation was performed at 36,000 r.p.m. for 5 h at 20°C using a Spinco SW41 rotor. Fractions (1 ml) were collected, a part (0.2 ml) of each fraction was withdrawn for radioactivity assays and the rest was dialysed against 1/10 SSC. Transformation was performed as described previously⁴ using 0.1 ml of the dialysed fractions as donor DNA and M0671 as a recipient. The number of transformants is the sum of Trp⁺ colonies produced with a total of 8×10^6 recipient cells. Δ, ³H-φ80 DNA; ○, transformants; ●, A_{260 nm}.

observed with DNA the molecular weight of which was between 1×10^6 and 2×10^6 (refs 3 and 4). Essentially the same results were obtained with unsheared and sheared λ pt(*trpA*⁺*B*⁺*C*⁺*D*⁺*E*⁺) DNA (Table 2).

Table 3 shows that the transforming activity increased linearly up to 5 μ g DNA per tube (0.5 ml) then levelled off, more or less the same pattern as observed when chromosomal DNA was used. The maximum transformation frequency with these DNA preparations was 2×10^{-5} to 8×10^{-5} . This is ten to thirty times greater than that observed with *E. coli* chromosomal DNA (1×10^6 to 5×10^6)¹⁻⁴. This higher efficiency is to be expected, since the concentration of the *trpB* gene in the ϕ 80pt DNA (also λ pt DNA) preparation was approximately eighty times greater than that in the chromosomal DNA preparation. The observed lower transformation efficiency than expected (eighty-fold increase) may have been due to recipient base sequence non-homology with the phage-specific base sequences which lie adjacent to the *trp* genes in the donor DNA. The biologically active material in the DNA preparation was sensitive to DNase (Table 3), eliminating the possibility that transduction by contaminating intact phages was the source of transformants. A ϕ 80 resistant (*tonB*) mutant strain was used as recipient for most experiments as a precaution to exclude such a possibility.

As Table 4 shows, the DNA from other types of ϕ 80 and λ phages, ϕ 80pt(*trpA*⁺*B*⁺*C*⁺), ϕ 80pt(*trpD*⁺*E*⁺), wild type ϕ 80 and λ , did not give any Trp⁺ transformants, clearly indicating that the presence of the *trpB*⁺ gene in the donor DNA preparation is the source of the transformation of the recipient's *trpB*⁻ marker. We next investigated the effect on specialised transformation of the genetic background of the recipient cells with respect to *recB* *recC* (ATP-dependent DNase) and *sbcB* (exonuclease I)¹⁷ genes, because generalised transformation of *E. coli* was shown to be affected by these genes¹. As we found in that system, the highest specialised transformation efficiency by ϕ 80pt(*A*⁺*B*⁺*C*⁺) DNA was observed in recipient strain M0639 (*recB21 recC22 sbcB15*) in which both DNases were missing. A small but significant number of transformants, approximately 20% of that observed with M0639, was obtained with M0649 (*recB*⁺ *recC*⁺ *sbcB15*).

TABLE 3 Transformation of the *trpB* mutation with various concentrations of DNA

λ pt(<i>trpA</i> ⁺ <i>B</i> ⁺ <i>C</i> ⁺ <i>D</i> ⁺ <i>E</i> ⁺)	648
λ pt(<i>trpA</i> ⁺ <i>B</i> ⁺ <i>C</i> ⁺ <i>D</i> ⁺ <i>E</i> ⁺), sheared	770
λ (cI26)	0
λ (cI26), sheared	3

Transformation was performed as described previously⁴ with a slight modification (see text) using M0671 as the recipient cells and DNA at a concentration of 5 μ g per tube (0.5 ml). The average molecular weight of sheared DNA from various phages was in the range of 8×10^6 to 9×10^6 . The number of transformants is the sum of Trp⁺ colonies produced with a total of 1.9×10^7 viable recipient cells.

Transformation occurred to a much lesser extent, approximately 5% of that with M0639, with B0650 (*recB*⁺ *recC*⁺ *sbcB*⁺). No transformants were obtained with M0668 (*recB21 recC22 sbcB*⁺), which is recombination-deficient. The absence of transformation in the Rec⁻ recipient indicates the participation of the host recombination system in the transformation process.

Mechanism of transformation

We have characterised the nature of the transformants obtained in our specialised transformation system. All the 120 tested Trp⁺ transformants obtained with sheared DNA were sensitive to ϕ 80 and did not produce any phage particles even after ultraviolet irradiation. Almost all (117 out of 120) the Trp⁺ transformants obtained with unsheared DNA were also sensitive to ϕ 80 and unable to produce phage after irradiation with ultraviolet light. These ϕ 80-sensitive Trp⁺ transformants produced by sheared and unsheared DNA were stable in their acquired Trp⁺ character. We could not detect any Trp⁻ segregants among more than 5,000 progeny grown from representative Trp⁺ colonies in a non-selective medium. We also tried to determine whether some Trp⁺ transformants still possessed the original *trp*⁻ markers in addition to the newly acquired Trp⁺ character. The *trp* operon and the *cysB* gene are known to be about 50% linked by cotransduction with P1 phage. The studies on specialised transduction had shown that integration events could place the newly added *trp*⁺ marker sometimes proximal and sometimes distal to the *trp*⁻ marker with respect to *cysB* (ref. 15). In the latter case, at least, it would be possible by P1 transduction readily to transfer the *trp*⁻ marker linked to *cysB* and without the *trp*⁺ marker. Twenty P1 lysates were prepared from random ϕ 80-sensitive Trp⁺ transformants (ten each from Trp⁺ transformants obtained with sheared and non-sheared DNA) and transduction was performed with a *trp*⁺ *cysB*⁻ recipient. All Cys⁺ transductants (more than 5000 Cys⁺ were tested) were Trp⁺, suggesting that the pre-existing *trp*⁻ marker was not present and had been replaced by a *trp*⁺ marker in all twenty transformants. These results, plus the fact that the transformation can be accomplished with sheared DNA suggest that the mechanism of transformation of the *trp* marker does not involve addition of the entire ϕ 80pt genome to the *E. coli* chromosome, but rather the replacement of the pre-existing *trp*⁻ marker by the *trp*⁺ marker present in the ϕ 80pt donor DNA. This is similar to what occurs in generalised transformation in *E. coli* and is in sharp contrast to specialised transduction

TABLE 5 Transformation of the *trpB* mutation on F' episome

Strain	Relevant genotype	Source	DNA	Concentration (μg per 0.5 ml)	Transformation frequency (trp^+ per 10^6 cells)
M0646	<i>F'lonB⁺trpB⁻/ΔtonBtrpABCDE</i>	None $\phi 80\text{pt}(\text{trpA}^+\text{B}^+\text{C}^+)$		0	<0.1
				1	7.4
				2	18.1
				5	56.7
				10	51.1
				10 (+DNase)	<0.1
		$\phi 80\text{pt}(\text{trpA}^+\text{B}^+\text{C}^+)$, sheared		1	20.3
				2	30.7

				10	78.1
				10 (+DNase)	0.4
				10	<0.1
				10 (+DNase)	<0.1
				10	<0.1
		$\lambda\text{pt}(\text{A}^+\text{B}^+\text{C}^+\text{D}^+\text{E}^+)$, sheared		10	<0.1
				10	<0.1
				10	<0.1
				10	<0.1

Transformation was performed as described previously⁴ with a slight modification (see text). Because of the temperature sensitivity of the F' replication, the cells (M0640 and M0646) were grown at 35°C and the selective plates were incubated at 30°C after transformation. The molecular weights of sheared DNA used here were 8.5×10^6 and 8.9×10^6 for $\phi 80\text{pt}$ and λpt DNA, respectively. DNase was added at a concentration of 10 μg per tube (0.5 ml). Trp^+ transformants were scored and the transformation frequency was calculated according to the total number of 9.4×10^6 and 2.7×10^7 recipient cells produced by M0640 and M0646, respectively.

with $\phi 80\text{pt}$ ¹⁵ and to transformation with λdgal DNA¹⁸, in which the entire $\phi 80\text{pt}$ and λdgal phage genomes are integrated into the host chromosome.

Transformation of *trp*⁻ on F' DNA

We have also accomplished specialised transformation of a *trpB* mutation located on episomal F' DNA instead of on the chromosome. A transformable strain (M0646) was constructed harbouring an F' which carried the *trp* operon (with a *trpB9579* mutation) plus adjacent chromosomal regions including the *tonB* locus, and with the *trp* operon and *tonB* locus deleted from the chromosome. When this strain was used as recipient for $\phi 80\text{pt}(\text{A}^+\text{B}^+\text{C}^+)$ and $\lambda\text{pt}(\text{A}^+\text{B}^+\text{C}^+\text{D}^+\text{E}^+)$ donor DNA, Trp^+ transformants emerged (Table 5). The frequency of the transformation (5×10^{-6} – 10×10^{-6}) was somewhat lower than the frequency obtained with the same donor DNA but with the recipient's *trpB9579* allele located on the chromosome. Since the F'-bearing recipient cells (M0646) contained a large deletion on the chromosome, from the *tonB* locus through the entire *trp* operon, the Trp^+ transformants seemed likely to be the products of recombination between the homologous *trp* regions on the F'DNA and the $\phi 80\text{pt}$ donor DNA. This was confirmed by our findings that (1) no Trp^+ transformants were obtained when we use recipients (M0640) harbouring the same large chromosomal deletion but lacking the episome (Table 5), and (2) the Trp^+ character could be transferred from Trp^+ transformants to a recombination deficient F' strain (M0868 *recA1 ΔtonBtrpABCDE*) together with other characters associated with the F', such as normal chromium resistance determined by the *tonB* locus^{19,20}. The basic characteristics of the system (Table 5) seem to be the same as those obtained with specialised transformation of the chromosomal *trp* marker.

Value of system

We have described, the transformation of a genetic marker (*trp*) on the *E. coli* chromosome or an F' episome by DNA isolated from specialised transducing phages carrying the *trp*⁺ marker. Although the frequency of the transformation ($\sim 10^{-5}$) is still somewhat lower than that obtained in generalised transformation with other bacterial species, for

example *Bacillus subtilis*, this system provides certain special advantages for studying various aspects of the transfer of genetic information, especially the mechanism of genetic recombination. The homogeneity of the genetic and molecular structure of donor DNA, stemming from its specialised transducing phage origin, is unique for bacterial transformation systems. The extensive genetic and biochemical background knowledge of *E. coli* and its related phages will be another advantage to this system. Of course, specialised transformation is not limited to *trp* genes but should also be applicable to any other well-characterised genes in *E. coli* such as *gal* or *bio* genes whose specialised transduction by λ phage is well established. Transformation of F' DNA with phage DNA reported here will provide a system in which not only the donor DNA but also the recipient DNA is composed of well defined relatively small molecular weight molecules. Such a system may be particularly useful in future biochemical and biophysical studies to examine the structural changes occurring in both recipient DNA and donor DNA during genetic recombination.

We thank S. Orenstein for technical assistance and J. Tamayo for preparing the manuscript. We also thank Dr P. Margolin for critically reading the manuscript and for discussions. This work was supported by a grant from the US National Science Foundation to M.O. S.D.C. was supported by a US Public Health Science research fellowship. M.O. is a US Public Health Service research career development awardee.

Membrane model for the circadian clock

David Njus, Frank M. Sulzman, & J. W. Hastings

The Biological Laboratories, Harvard University, Cambridge, Massachusetts 02138

The biological clock may be a feedback system involving ions and ion-transport channels.

RHYTHMS which will entrain to a 24 h light/dark cycle and persist under constant conditions with a period of about 1 d are apparently ubiquitous among eukaryotic organisms¹. A striking feature of these circadian rhythms is that the 'free-running' period, exhibited when there is no entrainment by environmental cycles, remains close to 24 h over a wide range of temperatures. (The 'free-running' period is implied in all subsequent references to the period, unless specified otherwise. There is a survey of circadian rhythms in ref. 1.) Most investigators believe that these rhythms are generated by a cellular biochemical system and that, though the details may vary from species to species, some fundamental mechanism is common to all.

Nevertheless, the molecular elements of this biological clock have proved elusive. To facilitate the search for the oscillatory system, it is helpful to consider models. Two conceptually different approaches have emerged. One conceives of the clock as a 'tape' with discrete biochemical events occurring in a strict sequence. In molecular terms, this has been interpreted as sequential gene expression: transcription of DNA proceeds, one gene at a time, at a controlled rate, as described most explicitly in the chronon model of Ehret and Trucco². Another approach, pursued by Pavlidis³⁻⁵, Pye⁶ and Sel'kov⁷, conceives of the clock as a biochemical network with self-sustained oscillations arising from feedback within the biochemical system. This notion can be traced to the oscillator theories of Pittendrigh and Bruce⁸ and the experimental work of Chance and associates^{9,10}.

Our model incorporates the network idea, but identifies ions and membrane-bound ion transport elements with the biochemical clock, and thus with the primary oscillations. Feedback arises from the effect of ion concentrations on the activities of the ion transport structures, which in turn affect ion distributions. (Obviously changes in ion concentrations imply changes in trans-membrane ion gradients and vice versa. However, the regulatory effects of ions relate most immediately to concentrations while ion fluxes are most readily discussed in terms of gradients. Therefore we use both descriptions, although they are equivalent.) The rate-limiting kinetics—either of ion transport or of change in transport activity—are postulated to be a function of the lipids, which in natural membranes are known to be adapted to the environmental temperature^{11,12}. Temperature compensation of the free-running period is hypothesised to be a consequence of this. Light affects the clock by open-

ing a membrane ion gate which may itself be photosensitive or be triggered hormonally from a remote photoreceptor.

Three concepts on which this model is based thus deal with the role of ions and membranes, the effect of light, and the importance of membrane lipids. To provide a more complete picture, we propose that the circadian change in membrane transport activity may involve the migration of membrane-intercalated particles within the plane of the membrane, and that time-dependent cooperative phenomena may account for accurate timekeeping and homeostasis.

Role of ions and membranes

Chemical agents which might alter the phase or period have been sought in the hope of pinpointing the molecular components of the clock. A few have been known for some time (D₂O¹³, ethanol¹⁴, arsenite and *p*-chloromercuribenzoate¹⁵), but these gave no clear indication of a unique target. More recent experiments implicate ions and membranes. Valinomycin (a highly specific carrier of K⁺) causes phase shifts in two systems, the bean plant *Phaseolus*¹⁶ and the dinoflagellate *Gonyaulax*¹⁷. Ethanol may act by changing the ionic permeability of biological membranes¹⁸; ethanol effects have now been demonstrated in *Phaseolus*¹⁴, *Gonyaulax*¹⁷ and the isopod *Excirolana*¹⁹. Although ion pulses are ineffective in several systems, this may be attributable to regulatory mechanisms for maintaining ion balances. K⁺ pulses do phase shift the rhythm in isolated eyes of the sea hare *Aplysia*²⁰ and lithium lengthens the period in the plant *Kalanchoe*²¹.

Ion involvement is also indicated by the fact that phytochrome, which may act as a K⁺ gate^{22,23}, apparently mediates the effect of light on the free-running period in *Phaseolus*²⁴ (28.1 h in red, 24.7 h in far red, 26.3 h in darkness or light of other wavelengths). Electric fields, which have an effect on some rhythms²⁵, should only affect spatially ordered systems, such as membranes and their surrounding charge distributions.

Rhythms are phase shifted by light pulses and entrained by light cycles, and the free-running period usually varies with the constant light intensity²⁶. In our model, light acts by perturbing ion concentrations (probably K⁺, since K⁺ and valinomycin pulses phase shift like light). The photoreceptors coupling to rhythmic systems are hypothesised to be photosensitive ion gates, as in visual systems and plant phytochromes. This allows for close coupling between the photoreceptor and the clock in unicellular organisms; specifically, a K⁺ flux through the photoreceptor gate augments or depletes the K⁺ concentration directly. In higher systems,

hormones may mediate between a specialized photoreceptor and the other cells²⁷. Consequently, the coupling hormone should induce a permeability change (possibly specific for K^+) in its target membrane. In support of this is Rensing's finding that the moulting hormone ecdysone phase shifts the rhythm in isolated *Drosophila* salivary glands²⁷. In *Chironomus* salivary glands, ecdysone acts by increasing the K^+/Na^+ ratio in cell nuclei²⁸. Circadian rhythm photoreceptors can be very sensitive and fast-acting, characteristics typical of photosensitive ion gates. A 1 ms flash phase shifts the fungus *Pilobolus*²⁹; an extraretinal photoreceptor of the sparrow is sensitive to 0.1 lux of green light³⁰. Winfree has found 1,000 ergs cm^{-2} applied over 2 min to be sufficient to saturate phase shifting in the fruit fly *Drosophila*³¹.

If the clock is a feedback oscillator with ions on one hand and membranes on the other, it must involve circadian changes in transmembrane ion fluxes. These fluxes, both passive and active, should be mediated primarily by membrane proteins. Activity changes in these proteins may involve either synthesis and degradation or activation and inhibition. Since protein synthesis is probably not required to drive the clock oscillation (see later), the clock function presumably involves activation and inhibition of transport proteins. The kinetics of the clock then must reflect both the kinetics of this activation and inactivation and the kinetics of the transport processes *per se*. But these rates probably depend also on the characteristics of the membrane lipids.

According to the 'fluid mosaic' concept of membrane structure³², membrane proteins are intercalated into the lipid bilayer and can move in the plane of the membrane through the fluid lipid matrix. Because the kinetics of this protein migration will depend on the fluidity of the membrane lipids, this migration constitutes a lipid-dependent process for activation and inactivation of membrane protein functions. A mechanism for temperature compensation of circadian rhythms is immediately suggested. The lipid composition of membranes is controlled to maintain a definite fluidity independent of temperature^{11,12}. The kinetics of protein migration should depend on the viscosity of the medium, so lipid adaption should render this temperature-compensated. The limited data available³³ suggests that the activities of some membrane-bound enzymes are temperature-compensated by the lipid adaption phenomenon, so the kinetics of protein-mediated ion transport may also be compensated in this way. Lipid adaptation also compensates the rate of passive ion diffusion through the lipid bilayer³⁴.

Characteristics of rhythms

It has long been known that observed rhythmic processes may not be an integral part of the timekeeper. Specifically, their suppression does not affect the clock. The only unmistakably clock-related experiments are those that concern shifting the phase or changing the period of the rhythm. Only those data will be considered in the ensuing discussion of clock properties.

A 24 h period is not easily derived from the relatively rapid processes encountered in biochemistry. The chronon model² relies on a 24 h transcription and recycling sequence, but the biochemistry has not been sufficiently elucidated to evaluate the model's kinetic feasibility. A biochemical oscillator might have difficulty with 24 h periods; experimentally studied systems have periods of no more than 15 min⁸ so a 100-fold frequency reduction is necessary. To circumvent this problem, Pavlidis has suggested that coupled oscillators may oscillate as a group with periods much longer than the individual units⁵. Spatial inhomogeneity in the timekeeper reactions may also lengthen the period. However, such a large frequency reduction should be critically dependent on the coupling parameters, and it is difficult to

imagine a biochemical system capable of maintaining the coupling constants within the limits required for an accurate period. The membrane model, by drawing on slower processes, such as lateral diffusion of proteins within the membrane³⁵⁻³⁷, can achieve 24 h periods more easily.

To provide for temperature compensation of the period, the chronon model² postulates aqueous diffusion processes to be rate-limiting, but the negative temperature coefficients shown by the algae *Oedogonium*³⁸ and *Gonyaulax*³⁹ are not accounted for. The network model of Pavlidis and Kauzmann⁴ postulates reduced enzyme levels at higher temperatures, attributing negative temperature coefficients to overcompensation. However, it cannot readily explain dual mode temperature compensation, such as that seen in *Euglena*⁴⁰, which has a period-length Q_{10} of 1.0 when grown autotrophically, but a Q_{10} of 0.93 when grown mixotrophically. The membrane model can attribute this to the fact that fatty acids of *Euglena* lipids vary with culture conditions⁴¹; negative temperature coefficients may be a consequence of overcompensation in the lipid adaptation process.

Circadian rhythms can be phase shifted by temperature steps and entrained by temperature cycles. (By convention, a temperature step is a prompt change in the environmental temperature. A temperature pulse involves a step followed (usually 12 h later) by an opposite step returning the system to its initial temperature. The repeated application of temperature pulses (usually with a 24 h period) is called a temperature cycle.) In *Drosophila*, entrainment by 24 h temperature cycles follows directly from the form of the phase response curve for single temperature steps⁴². A temperature cycle apparently acts as a series of independent steps, implying that phase shifting due to a temperature step is completed within 12 h. Experimentally, the direction of the temperature change determines the direction of the phase shift. For a temperature step up, a phase advance occurs as if the clock had run fast for awhile; for a step down, a phase delay occurs^{40,42-47}. This indicates that the temperature compensation process requires several hours to complete. In our membrane model, the lipids must adjust to a change in temperature with a time constant on the order of hours. Lipid compensation requires about 4 h in stationary phase *E. coli*⁴⁸, and earthworms injected with an extract from cold-adapted earthworms change their lipid saturation within 3 h⁴⁹.

In some systems, the overt rhythm is lost at low temperatures and the mechanism seems to settle into a unique phase point; when the temperature is raised, the rhythm resumes with a phase defined by that time^{39,40,50}. The membrane model provides an interpretation: the temperature is below the adaptation range for the lipids in the membrane, which then will undergo a transition to a more condensed phase. This should cause the ion gradients to fall into the pattern characteristic of the unique phase point; it is interesting that in *Gonyaulax* both low temperature and bright light hold the system at the same point, CT 12. (Circadian time (CT) is defined by dividing the period into twenty-four equal portions. CT 0 is chosen as the beginning of the light period or its equivalent in a free-running system.)

To analyse the effects of light on rhythms, a simple two-parameter example is helpful. Assume that the rhythm involves just one ion and its associated transport pathways. The trans-membrane ion gradient, x , will oscillate as in Fig. 1d. Membrane transport, y , will also vary but, for simplicity, let it have only two states (Fig. 1b). Light has the effect of depleting the ion gradient since it opens an ion gate. Therefore, a light pulse dropping the gradient to x_0 may have two effects. Applied before CT 18, it will cause a phase delay because the membrane is in the active mode and x will repeat its accumulation. A light pulse given after CT 18 will cause a phase advance since the membrane is in the passive mode and x will skip ahead in its discharge.

This simple illustration will not give quantitative agreement with phase shifting data. For a proper analysis of the two-dimensional oscillator, the dynamical equations should be written as $dx/dt = f_1(x, y)$ and $dy/dt = f_2(x, y)$. Light of intensity, L , acts on the system to deplete the gradient x . Since this is a passive flux, it should proceed at a rate proportional to x and to some function of the light intensity $f_3(L)$. Therefore, dx/dt must be modified to include the light effect: $dx/dt = f_1(x, y) - x f_3(L)$. An analysis of a particular set of equations of this type quantitatively reproduces the effects of light on the *Drosophila* system including the influence of the light intensity on the period^{3,4}. While these equations are not unique in their ability to account for the data, they do establish the quantitative plausibility of this sort of system. Of course, any network model can be fit to these equations, but the phase shifting caused by the rapid destruction of x is particularly descriptive of the depletion of ion gradients.

FIG. 1 Hypothetical oscillations in a simple one-ion system with only two membrane states. A light pulse applied just before CT 18 results in a phase delay since it brings the ion-membrane system to a state equivalent to that at about CT 13. Similarly, an identical light pulse just after CT 18 results in a phase advance. Maximum phase shifts are obtained at night.

The cellular clock couples biochemically to diverse expressed rhythms possessing various phase angles. Control of some processes, such as leaf movement in *Albizia*, can be readily attributed to ions²³, and rhythms in membrane processes such as photosynthesis, respiration, phototaxis and excitability could depend directly on ion variations. Some rhythmic processes, such as bioluminescence in *Gonyaulax*, involve, in part, variations in enzyme and substrate levels^{51,52}. Reconciling this with a membrane model is more difficult, although variations in enzyme levels could be achieved through ion-mediated activation and inactivation, without *de novo* synthesis. However, ions might also act by stimulating the production of inducers—perhaps for all rhythmically expressed proteins, perhaps only for specific rhythmically-expressed RNA polymerases. A diurnal variation in polymerases has been reported⁵³. The induction hypothesis allows genes to be regulated in groups, which would facilitate control of several complex processes associated with one circadian rhythm. Furthermore, this would make mRNA synthesis a driven rhythm rather than a part of the clock itself, explaining the failure of RNA synthesis inhibitors to phase shift the rhythm.

Speculations and implications

In considering the detailed structure of the membrane, we could imagine a simple model in which passive and active transport channels respond directly to changes in ion concentrations so that they flip back and forth into on and off modes. This probably has too fast a response time and would generate rapid oscillations as observed in mitochondria⁵⁴. Instead, we have suggested a requirement for lateral diffusion of protein in the membrane^{35,36}. Particles seen by freeze-fracture electron microscopy exhibit characteristic arrangements and sizes in differentiated membrane regions⁵⁵⁻⁵⁹ correlated with pH and other ion concentrations^{37,55,60,61}. We propose that these particle distributions can be regulated by oscillating ion concentrations and may themselves then regulate the ion concentrations to drive the oscillation. This is easy to imagine for structures such as cell junctions; ATPases and other enzymatic functions might also be activated and inactivated in this way. Furthermore, this process of constructing particle arrays should be relatively slow.

At the risk of conveying a simplistic and overly specific image, we present in Fig. 2 a diagrammatic version of our membrane timekeeper in the style of Singer and Nicolson's 'fluid mosaic' membrane³². This shows changes in both particle arrangements and sizes, caused by the ion distributions. The state of these particles, in turn, determines the direction and activity of membrane transport. While only one ion and a corresponding set of transport proteins is represented, other ions and other transport systems may be tied in, forming a system of coupled oscillators. A photoreceptor which serves as a K^+ gate is included in this picture; in other cases, this might be a hormone-triggered ion gate.

Circadian rhythms persist in enucleate cells^{62,63} and seem to be unaffected by many nucleic acid and protein synthesis inhibitors^{50,64-67}. Among such inhibitors only cycloheximide has been shown to affect a circadian rhythm⁶⁸ although the period change was small considering the degree of protein synthesis inhibition. The fact that inhibition of protein synthesis does not have a larger and more universal effect suggests that the clock keeps time relatively independently of precise enzyme levels. This is particularly compatible with the membrane model, since it does not require precisely balanced enzymic activities, especially to achieve temperature compensation.

A minimal dependence on stochastic fluctuations in enzyme levels has adaptive advantage in a clock mechanism and is an example of the principle of homeostasis: circadian clocks are insensitive to the perturbations they normally encounter⁶⁹. Time-dependent cooperative phenomena provide an attractive means for achieving timekeeping precision and homeostasis. The sigmoid curve characteristic of cooperative phenomena provides a more precise definition of time and is less sensitive to fluctuations in enzyme, metabolite or threshold levels than are functions based on non-cooperative processes. Indeed, regulation in biological systems is commonly associated with cooperativity^{70,71}. The formation of particle arrays ought to show time-dependent cooperativity, since it should be a nucleation process analogous to crystal growth.

A model should provide insight for further research. Our model makes specific and testable statements about the ionic nature of the fundamental oscillator, the action of light, the role of lipids in temperature effects, the insensitivity of the clock to fluctuations in enzyme levels, and the role of membrane-intercalated particles in maintaining self-sustained oscillations in ion concentrations.

In clock mutants, altered proteins might be involved in ion transport or lipid metabolism. Phenotypically, mutants might have altered ion transport properties, defects in membrane particle aggregation, or differences in lipid fluidity.

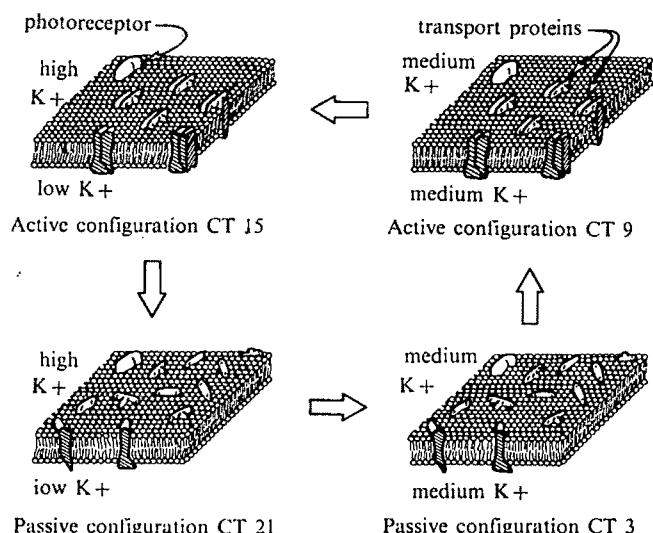

FIG. 2 Schematic representation of the way in which a fluid mosaic membrane³² might keep time. This illustrates the simple one-ion oscillator discussed earlier.

Membrane lipids can also be changed nutritionally or by inhibiting the lipid adaptation mechanism and changing the temperature. Changes in the period should correlate with changes in the lipids; the time course of lipid compensation in rhythmic cells should be determined.

This model predicts that the photoreceptor is membrane-bound and functions as an ion-gating device. In unicellular organisms, phase shifting with light should cause a change in the ion distributions. Mediating hormones in higher animals should produce changes in the ionic permeabilities of their target membranes. The response of membrane transport systems to ion concentrations *in vitro* can be analysed to see whether these systems are capable of self-sustained oscillations with 24 h periods.

Ferritin labelling and freeze-fracture electron microscopy should be useful in observing circadian rhythms in the arrangement of membrane-intercalated particles.

In summary, we have described a membrane model for the biological clock, which accounts qualitatively for many of its characteristic features. Ion concentrations and ion transport channels function as a feedback system to generate self-sustained circadian oscillations. Light acts on the rhythm either directly or through hormonal coupling to deplete trans-membrane ion gradients. Temperature compensation of the free-running period is a consequence of the temperature adaptation of membrane lipids. We have speculated that the timekeeping involves time-dependent cooperativity and the rearrangement of membrane-intercalated particles.

We thank Drs M. W. Karakashian, N. R. Krieger, M. D. McDaniel, D. Mergenhausen, R. E. Schmitter and B. M. Sweeney for stimulating discussions and criticism. This work was supported by a grant from the National Institutes of Health.

Infrared observations of Comet Kohoutek before perihelion passage

I REPORT in this letter broadband observations at 10 μm and 20 μm of the nucleus of Comet Kohoutek. These measurements were taken about 1 week before perihelion, while the comet was about 0.35 AU from the Sun. Table 1 summarises the results, which show that the comet was an intense infrared object, magnitude about -5 , and that the nuclear material responsible for the infrared emission heated up rapidly as the comet sped toward the Sun.

10- μm magnitude to be -4.56 relative to α Boo. (The extinction correction at 10 μm was 0.15 mag per air mass.) The uncertainty in my results arises primarily from the uncertainty in the standard magnitudes for α Boo and α Sco and also from the temporal variation in the infrared extinction. I estimate both these effects to contribute an error of no more than ± 0.03 mag in the final results.

Table 1 shows that as the comet grew brighter at about 10 and 20 μm , the colour difference decreased as expected from solar heating of the solid material in the nucleus. This colour change is reflected in the sharp rise of the colour temperature. The derived colour temperatures are above those expected from a grey-body sphere heated by sunlight at the same solar distance as the comet. (For example, at 0.33 AU the expected temperature is about 525 K.) Similar

* Taken from the Comet Kohoutek ephemeris of D. K. Yeomanis.

I obtained these measurements with the 1.3-m telescope at Kitt Peak National Observatory. The infrared detector was a germanium bolometer with a beam size of 24 arcs. The chopping secondary of the telescope was adjusted to give a beam separation of 38 arcs in declination. During the observations, I centred the beam on the position of peak infrared emission; this location defined the infrared nucleus of the comet. The magnitudes in Table 1 refer only to the infrared flux originating from the portion of the comet within the beam's area. As I found the comet's infrared emission extended over an area greater than 1 arc min, the comet's total integrated infrared magnitudes must be greater than those listed in Table 1.

All magnitudes are relative to the standard star α Boo. Since α Sco was conveniently close to the comet on the dates of observation, I also compared the comet to this star. The advantage of using α Sco was that it suffered from essentially the same atmospheric infrared extinction as the comet, so little correction in the relative magnitudes was necessary. I adopted -4.82 as the 20- μm magnitude of α Sco¹, and I measured its

excessive infrared colour temperatures have been noted for Comet Ikeya-Seki² and Comets Bennett and Tago-Sato-Kosaka³. This colour temperature anomaly is probably due to the spectral behaviour of the absorptive efficiency of the radiating grains in the nucleus². The data in this letter are not sufficient to identify the character of the grains but observations made as the comet streaks from the Sun may answer this important question.

I acknowledge the help of Dr D. E. Kleinmann.

Detection of methyl cyanide in Comet Kohoutek

Most current models of comets assume that the nucleus is an icy solid body containing fairly complex parent chemical compounds which sublimate and dissociate to provide the radicals and simple molecules that have been observed in cometary spectra¹. Optical spectra show the presence of CN, CO⁺, CH, NH, OH and many others²; proposed parent molecules have included H₂O, HCN, HNCO, CH₃CN and H₂CO³. Previous attempts to detect H₂CO and H₂O were unsuccessful, probably due to excessive beam dilution^{4,5}. Here we report the first direct detection of a parent molecule, methyl cyanide (CH₃CN), at a wavelength of 2.7 mm in Comet Kohoutek (1973f). At the same time we were unable to detect either CN or CO at similar wavelengths.

Observations were made with the NRAO 11-m radio telescope at Kitt Peak, Arizona. The antenna had a half-power beamwidth of 67 × 63 arc s and a main beam efficiency of 0.55 for these observations. The first stage of the receiver is a double sideband Schottky-barrier crystal mixer with a 1,390 MHz IF; the overall system temperature is about 1,450 K single sideband. Spectral line data were taken using three filter banks: 256 contiguous 250 kHz filters, 50 contiguous 250 kHz filters, and 50 contiguous 100 kHz filters; all filter banks had the same centre frequency. The receiver was calibrated with a rotating chopper wheel; the calibration was checked by observing spectral lines of CO and CN with known strength in the galactic sources W51 and DR21. All data were reduced with the NRAO advanced on-line computing system⁶.

Table 1 is a summary of the observations. All values shown

sideband. After correction for the geocentric velocity expected, we calculated the rest frequencies given in the first two lines of Table 2. We are confident that the emission is from the comet nucleus only, as spectra from several days at different equatorial coordinates and different geocentric velocities all show the lines. Also, no lines were seen when we observed one arc min north, south, east and west of the nucleus. On December 3 we observed the same right ascension and declination as on December 1 to check for background sources; this also produced negative results. Finally, no emission was seen at several points along the comet's tail. Searches for CN and CO emission at several positions showed no detectable signals; the best upper limits are given in Table 2.

The two lines that we observed can be identified with 6,3 to 5,3, and 6,0 to 5,0 vibrationally excited transitions of CH₃CN at 110,709.55 and 110,712.22 MHz (ref. 7). Our calculated rest frequencies agree perfectly in line separation but are systematically 0.2 MHz high, or 0.54 km s⁻¹ low in geocentric velocity. This difference is probably not significant in view of the quoted errors. Methyl cyanide has previously been observed in Sgr A and Sgr B where its column density is comparable to that of CN (ref. 8).

The observed antenna temperatures may be used to calculate the optical depth and hence the column density of methyl cyanide. The exact lifetime of the CH₃CN molecule until photo-dissociation, and thus the distance from the cometary nucleus over which it should exist, are not known; a reasonable approximate value is 10⁴ km (refs 3, 9, 10). At a geocentric distance of 1.33 AU the region would subtend approximately 21 arc s and fill 0.06 of the antenna beam. The observed antenna temperature T_A is related to

TABLE 1 Observations of Comet Kohoutek (1973f)

UT Date (1973)	RA	1973.9 Dec.	Geocentric velocity (km s ⁻¹)	Geocentric distance (AU)	Heliocentric distance (AU)	Frequency range observed (MHz)

December 2	13 h 47 min	-20°37'	-33.2	1.34	0.85	(112,471-112,535) (115,251-115,315)
December 3	13 h 54 min	-21°06'	-32.1	1.32	0.83	(110,691-110,755) (113,472-113,536)
December 4	14 h 01 min	-21°34'	-31.0	1.30	0.81	(112,471-112,535) (115,251-115,315)
December 5	14 h 09 min	-22°02'	-29.8	1.29	0.79	(110,690-110,754) (113,471-113,535)

are averages over about 6 h of observation time daily. The ephemeris was supplied by T. Clark (Goddard Space Flight Centre) and calculated from elements published in IAU Circular No. 2588. The position of the comet was checked with an optical telescope attached to the antenna; it agreed with star positions from the FK4 catalogue within 10 arc s. The radio data were taken in a beam-switching mode—alternating integrations for 30 s on the source and on a position 30 arc min greater in right ascension. Two frequency ranges were covered simultaneously since the receiver responds to both sidebands. About half the data were taken looking through the fabric dome surrounding the telescope in order to protect the telescope surface from solar heating; the dome loss, about 40%, was taken into account when averaging the individual spectra.

Figure 1 shows spectra from the 100 kHz filter banks on December 1, December 5 and on both days combined; two lines are clearly visible in emission. They appear somewhat broadened by the filter response and by artificial smoothing. These lines were also detected in both 250 kHz filter banks. Also shown is the expected position of the CN line in the upper sideband. A shift in the local oscillator frequency showed that the observed lines were in the lower

the optical depth τ by

$$T_A = B\eta_n T_c \{1 - \exp(-\tau)\} \simeq B\eta_n T_c \tau \quad (\tau \ll 1) \quad (1)$$

where B is the beam dilution factor, η_n is the antenna main beam efficiency, and T_c is the temperature of the cometary gas. T_c is given by

$$T_c = \left(\frac{mc^2}{2k} \right) \left(\frac{\Delta\nu}{\nu} \right)^2 \quad (2)$$

where m is the mass of the molecule, c is the velocity of light, k is Boltzmann's constant and $\Delta\nu$ is the line half-width at 1/e intensity at the frequency ν . For $\Delta\nu = 0.12 \pm 0.04$ MHz and $\nu = 110,710$ MHz, $T_c = 263 \pm 160$ K for CH₃CN; the equilibrium temperature for a black body at a heliocentric distance of 0.83 AU is 306 K. Substituting into equation (1) $T_c = 263 \pm 160$ K, $T_A = 0.6 \pm 0.1$ K, $B = 0.06$, and $\eta_n = 0.55$ we obtain $\tau = 0.07 \pm 0.04$ for the 6,0 to 5,0 line. Similarly, the optical depth of the 6,3 to 5,3 transition is $\tau = 0.05 \pm 0.03$ and the CN and CO upper limits are $\tau \leq 0.06$ and $\tau \leq 0.15$, respectively, assuming the same T_c .

TABLE 2 Results

Observed rest frequency (MHz)	Molecule	Transition	Antenna temperature (K)	Intrinsic line half-width at 1/e intensity (km s ⁻¹)	Observed position
110,709.7 ± 0.2	CH ₃ CN	6,3 → 5,3	0.4 ± 0.1	0.32 ± 0.11	nucleus
110,712.4 ± 0.2	CH ₃ CN	6,0 → 5,0	0.6 ± 0.1	0.32 ± 0.11	nucleus
110,712.4	CH ₃ CN	6,0 → 5,0	≤ 0.25		tail
113,491.0	CN	1 → 0	≤ 0.20		(5' from nucleus)
115,271.2	CO	1 → 0	≤ 0.50		nucleus
					nucleus

The optical depth τ for a symmetric rotor such as CH₃CN is³

$$\tau = \frac{16\pi^2 N f_v h^{3/2} \mu^2 \nu^2 B C^{1/2}}{3c \Delta \nu (k T_c)^{5/2}} \frac{\{(J+1)^2 - K^2\}}{(J+1)} \cdot \exp(-W/T_c) \quad (3)$$

where h is Planck's constant, N is the column density (molecules cm⁻²), f_v is the fraction of molecules in the same vibrational state ($\sim 1/2$), B and C are the molecular rotation constants (both 9,199 MHz), μ is the dipole moment (3.92×10^{-18} e.s.u. cm), and W is the sum of vibrational and rotational energies of the upper level divided by Boltzmann's constant ($W = 500$ K). For the 6,0 to 5,0 transition, $\tau = 2.3 \pm 1.6 \times 10^{-18}$ N, and thus $N = 3.0 \pm 2.1 \times 10^{16}$ molecules cm⁻² averaged over the cloud diameter of 2×10^4 km. The 6,3 to 5,3 transition is theoretically weaker by a factor of 0.75, which agrees within errors with the observed ratio of 0.67. This transition gives $N = 2.9 \pm 2.1 \times 10^{16}$ molecules cm⁻².

Adopting the fluid dynamic model in which the molecular density is proportional to r^{-2} out to a critical radius r_c

where the molecules are destroyed⁴, then the number fraction b of CH₃CN molecules is given by

$$b = \frac{N v r_0}{4 Z R^2} \quad (4)$$

where v is the molecular velocity (4×10^4 cm s⁻¹), Z is the comet's gas production rate in molecules cm⁻² s⁻¹ rad⁻² and R is the radius of the icy nucleus. Substituting typical values of $Z = 3 \times 10^{18}$, $R = 2 \times 10^6$ cm and $r_0 = 10^9$ cm, we find for CH₃CN that $b = 0.025 \pm 0.018$.

In conclusion, the detection of methyl cyanide in the nucleus of Comet Kohoutek at a reasonable abundance has provided the first direct confirmation of the parent-daughter molecule hypothesis. Future observations of this comet as it passes perihelion are most desirable and should show changes in the density of such heavy molecules and their dissociation products.

Cosmic-ray energy spectrum from 10¹⁵ to 10¹⁸ eV

THE problem of establishing the primary cosmic-ray energy spectrum at energies $\geq 10^{15}$ eV, a region of great astrophysical interest, depends for its solution on the relation between the size and total primary energy of extensive air showers. This is because the experimental data are directly related to extensive air shower size spectra, which must then be converted to a primary energy spectrum. The necessary conversion depends, among other things, on the physics of the hadronic part of the cascade and on the primary composition in an energy region in which such information is only

available from extensive air showers themselves. The primary energy spectrum above 10^{15} eV is thus less well established than it is, for example, below 10^{12} eV, where direct measurements have been made, both of cosmic-ray primaries and of individual hadronic interactions.

In the absence of independent knowledge of primary composition and of properties of high energy interactions above 10^{12} eV, a demonstration that the relation of shower size to primary energy is, to some extent, independent of these features would be valuable. Such model independence is suggested by comparison of the calculation presented here, which assumes heavy primaries and Feynman scaling to relate shower size to primary energy, with calculations based on more conventional assumptions.

Various recent calculations (refs 1-3 and other papers presented at the Denver Conference) of extensive air shower (EAS) properties show that Feynman scaling for hadronic interactions appears to break down between $\sim 1,000$ GeV and $\sim 10^6$ GeV if the primary cosmic-ray beam is predominantly protons at EAS energies ($E \gtrsim 10^6$ GeV). It has been suggested, however, that if the primaries are predominantly heavy nuclei (for example, Fe) and if intranuclear cascading and an increasing p-air cross section are taken into account, then an approximate form of Feynman scaling (modified to allow for an increasing cross section) may hold from Intersecting Storage Rings (ISR) to EAS energies (refs 1, 2 and 2a). Here I report the use of a cascade calculation based on these assumptions to calibrate the Chacaltaya measurements of size against depth⁴⁻⁶ and obtain a primary energy spectrum from 10^{15} to 10^{18} eV. The spectrum obtained in this way is surprisingly close to that obtained from entirely different assumptions by the authors of refs 4, 5 and 6. (The authors of ref. 6 point out that, in view of the disagreement (around 10^{17} eV) between their results and those of refs 4 and 5, theirs are preliminary.)

Fig. 1 Comparison between data and calculations of shower size against depth. Each calculated curve is normalised at one depth only (600 g cm^{-2}) to the data. *a*, Intensity ($\text{cm}^{-2} \text{ s}^{-1} \text{ sr}^{-1}$); *b*, corresponding total primary energy per nucleus, E_0 (GeV). ▲, refs 4 and 5.

Specifically, I assume pure iron primaries over the range of the Chacaltaya measurements, Feynman scaling⁷ from ISR data for the number distributions of pions produced in hadron-hadron interactions, and the model of Fishbane, Newmeyer and Trefil⁸ for intranuclear cascading. This picture of the primary composition is almost certainly oversimplified and possibly incorrect⁹ and the assumptions about hadronic interactions at EAS energies may have to be modified. Nevertheless, the quality of the fit to the Chacaltaya measurements of size against depth obtained in this framework makes it worth using it to convert the Chacaltaya size spectra to an energy spectrum.

In the spirit of this simple approach I treat an iron nucleus of total energy E_0 as a superposition of nucleons each of energy $E_0/56$. The size of the electromagnetic component of the shower is computed at various atmospheric depths as a function of E_0 using the cascade calculation described^{2a}.

The Chacaltaya shower development data⁴⁻⁶ were obtained by taking constant intensity cuts in the integral size spectra at various shower zenith angles, corresponding to different atmospheric depths. The minimum depth is thus the vertical depth at Chacaltaya, 550 g cm^{-2} . I obtain the energy calibration here by fitting the observed size at 600 g cm^{-2} to the calculated shower size at this depth for each intensity. The calculated shower development curves are compared with the data of refs 4 and 5 in Fig. 1. It is clear from the agreement between the curves and the data in Fig. 1 that a different choice of normalisation depth would produce

Fig. 2 Data points represent the primary integral energy spectrum obtained from Fig. 1 as described in the text. The normalisation obtained at 10^{17} eV from the EAS calibration of refs 4 and 5 is also shown as a ▲. ---, Extrapolations of Fe and $p + \alpha$ spectra measured at lower energies in balloon experiments (refs 10 and 11).

little change in the primary energy assigned to any of the intensities. Similar good agreement between calculated and observed shower development is also obtained for the data of ref. 6 (not shown here).

Figure 2 shows the integral energy spectrum of EAS primaries obtained from this analysis. A similar analysis has been carried out for the data of ref. 6. Both the magnitude and the slopes obtained agree within errors with those determined in refs 4-6 assuming predominantly proton primaries and using constant cross section and power law multiplicity for the number of particles produced in hadron-hadron collisions. In particular, the slope of the primary spectrum is steeper above 10^{15} eV than at lower energies ($\gamma \sim 2.2$ for the data of refs 4 and 5 and $\gamma \sim 1.8$ above 10^{17} eV for ref. 6). The similarity of primary energy spectra obtained under these two extreme sets of assumptions gives one confidence that the energy spectrum is not subject to appreciable uncertainties arising from ignorance of primary composition or of hadronic production mechanisms in this energy range (provided one uses a picture that fits the data on size against depth for EAS).

For comparison I show in Fig. 2 the data of the Goddard Space Flight Center on iron¹⁰ (plotted as number of Fe with total energy $>E$) and $p + \alpha$ primaries¹¹ (solid lines) and their extrapolations (dashed lines). Clearly, if the primary spectrum above $\sim 10^{15}$ eV is all iron, the slope of that spectrum is unlikely to have any relation to the mechanism¹² that may be responsible for the flat iron spectrum at low energy.

I thank G. B. Yodh for discussions and P. K. MacKeown for making available the results of ref. 6. This work was supported in part by the National Science Foundation.

Raman backscatter of Laser radiation from the stratosphere

RAMAN-shifted backscatter of laser radar radiation from atmospheric constituents in the troposphere has been reported¹⁻³. Signals from nitrogen have been detected up to heights of about 6 km and there have been indications of backscatter at even greater heights⁴. Oxygen and water vapour have also been the subject of tropospheric Raman investigations, generally using frequency doubled ruby (0.3472 μ m) as the laser transmitter.

Results outlined below show that the Mark II laser radar

system at the University of the West Indies, Kingston, Jamaica, can extend the range of Raman investigations on atmospheric nitrogen well into the stratosphere. This system has been described⁵ and is unchanged except for the introduction of new digital counting circuitry. A pulsed ruby laser transmits at a wavelength of 0.6943 μ m and the Raman return from nitrogen is received at 0.8284 μ m. The returning radiation passes through an interference filter (bandwidth 1.5 nm) on to photomultipliers and then, by way of a suitable pulse discriminating and amplifying system, to counters which give a digital display of the photon count for gated 2 km and 4 km intervals. Although there is some disadvantage in scattering cross section and photomultiplier sensitivity at these wavelengths, data obtained indicate that signals can be detected up to a height of about 45 km.

In order to examine statistically the performance of the system, the photon counts from the different gates have been related to atmospheric density values obtained from balloon measurements carried out by the local Meteorological Office and from the US Standard Atmosphere Supplements for 15° N⁶. The laser radar site is at Kingston (18.0° N) and is approximately 10 miles from the point at which the Meteorological Office sends up balloons. Comparisons have had to be made with the US Standard Atmosphere as the balloons used by the Meteorological Office burst in the region of 30 km. In addition, the accuracy of balloon measurements rapidly diminishes above 20 km.

The received photon count C is expected to be proportional to the ratio $(\rho_0 T_V T_D / h^2)$ where ρ_0 is the atmospheric density; T_V the atmospheric transmissivity at 0.6943 μ m, T_D the atmospheric transmissivity at 0.8284 μ m, and h the distance from transmitter to the effective point of scatter. As it is not possible to determine directly the constant of proportionality, the ratio $(Ch^2 / \rho_0 T_V T_D)$ has been normalised to unity at the gate interval 22-24 km. (This point was chosen for technical reasons associated with the equipment and photon counting method.) For perfect correspondence of C and ρ_0 , the ratios for all other gates should be unity within the limits of probable error. Figure 1a shows the photon counts obtained from an investigation on the night of August 25, 1973, when 2,200 laser firings were made, compared with atmospheric density values obtained from the US Standard Atmosphere Supplement (annual average).

FIG. 1 Photon counts obtained on the night of August 25, 1973, compared to (a) US Standard Atmosphere Supplement for 15° N; (b) local radio-sonde measurements. The observations have been fitted at a height of 22 km.

This comparison is appropriate since the atmosphere at this latitude is remarkably constant. Figure 6 shows the same data related to radiosonde measurements made by the Jamaican Meteorological Office at 0700 h EST on August 26, 1973. In estimating the performance of the laser radar system, it must be noted that at a height of 28 km the pressure is in the region of 15 mbar, and radiosonde measurements of pressure can be in error by as much as 15%. There are also error contributions due to temperature and height measurements.

There is close agreement between the laser radar measurements and data from the Meteorological Office and the US Standard Atmosphere Supplement. The error bars show the standard deviation of the laser radar measurements based on the counting statistics. Most points are within one standard deviation of unity and none are much more than two distant from it. No allowance has been made for any possible errors in the radiosonde data. We think the results confirm that useful Raman signals from atmospheric nitrogen can be detected by the Mark II system up to a height of about 40 km. In the final gate (44–48 km) the signal-to-noise ratio was approximately unity whereas for the 36–40 km gate it was greater than 3.

We thank the Jamaica Meteorological Service for making radiosonde data available. Operation of the Mark II laser radar system has been partially financed by the Air Force Cambridge Research Laboratories, Office of Aerospace Research, United States Air Force.

Caesium-137 as a water movement tracer in the St George's Channel

CALCULATIONS based on recent measurements of the distribution of ¹³⁷Cs in the St George's Channel show that the residual (non-tidal) flow is slightly lower than previous indirect estimates suggested. The contribution of turbulent mixing to the transport of dissolved and particulate material in these waters may also be calculated directly from caesium measurements.

Study of the isohaline patterns and of drifter movements shows that there is a residual flow of water from south to north in the Irish Sea system. It is, however, difficult to arrive at an accurate mean value for this flow because of the effects of turbulent mixing in modifying the isohaline pattern, and the effects of wind on surface drifters. Available current meter measurements and subsurface drifter experiments are insufficient in number to give long term mean values for such a large scale low velocity flow.

Knudsen¹ approached the problem by application of the continuity conditions for water and salt. Since he neglected the

Salinities from Bowden⁴. Caesium values (May 1972) from Jefferies *et al.*⁶; others from unpublished data of this laboratory. Units: Salinity (S) parts per thousand by weight; ¹³⁷Cs pCi⁻¹ (equivalent to Ci km⁻²).

transport of salt by turbulent mixing the results he obtained (400 to 700 km yr⁻¹) are rather higher than those obtained by methods which take account of this process². Proudman³ correlated the passage of salinity anomalies at various observation points in the Irish Sea system and obtained a travel time corresponding to about 400 km yr⁻¹; Bowden⁴ utilised improved data to obtain a value of about 150 km yr⁻¹ by a similar method. Proudman⁵ derived an estimate for the ratio of the flow velocity to the diffusion coefficient normal to the flow direction by fitting a parabola to the observed isohalines between Holyhead and Dublin; this approach gave estimates of between 750 and 270 km yr⁻¹ depending on the value assumed² for the diffusion coefficient.

Bowden² extended Knudsen's method by including diffusive terms in the equation of continuity of salt. The continuity equations he obtained are as follows.

For water

$$X_1 U_1 + W = X_2 U_2 \quad (1)$$

(where X_1 and X_2 are the south and north boundary cross-sectional areas respectively (Fig. 1), U_1 and U_2 are the corresponding mean advective velocities (northwards positive) and W is the net fresh water input to the channel from precipitation, evaporation and runoff).

For salt

$$\rho_1 X_1 U_1 S_1 - \rho_1 X_1 \left(K_z \frac{\partial S}{\partial x} \right)_1 = \rho_2 X_2 U_2 S_2 - \rho_2 X_2 \left(K_z \frac{\partial S}{\partial x} \right)_2 \quad (2)$$

where ρ and S represent densities and salinities respectively and the second term on each side of the equation represents the mass flux of salt through the appropriate cross section by turbulent mixing. This equation may be simplified by assuming that $\rho_1 = \rho_2$ and K_z is constant: these are reasonable assumptions for the St George's Channel, where the north and south cross sections are similar.

Because K_z , U_1 and U_2 are unknown it is not possible to obtain a direct solution by considering only equations 1 and 2. To circumvent this problem Bowden² assumed K_z at the southern boundary to lie between 0 and 8.8×10^6 cm² s⁻¹. Using this assumption he estimated that U_1 lay between 126 and 610 km yr⁻¹ and U_2 between 111 and 438 km yr⁻¹.

Study of the movement of ¹³⁷Cs, released into the Irish Sea as a component of the low level radioactive waste pro-

duced at the Windscale plant of British Nuclear Fuels Ltd, provides a means to the direct solution of this problem. Caesium-137 is an almost ideal tracer for seawater movement as it has a long half-life (~ 30 yr), does not adsorb significantly on to sedimentary material and is easily detected at very low concentrations. Since the amounts of tracer added are several orders of magnitude less than the seawater concentration of natural (non-radioactive) caesium ($0.3 \mu\text{g l}^{-1}$), the presence of the tracer has no influence on the density or other physical properties of the seawater. It is, however, necessary to separate the tracer from the natural background activity of seawater due to ^{40}K (200 pCi l^{-1}) and to concentrate it for counting. In the present work this is done by adsorbing the tracer from up to 10 l of seawater onto a small volume (1 ml) of copper ferrocyanide. The retention of caesium is essentially complete (98%) whereas potassium is not adsorbed. Data for three complete surveys of the Irish Sea system have been obtained by this method (Table 1); the results for February 1973 are shown in Fig. 1. The results

FIG. 1 Distribution of caesium-137 in the St George's Channel and Irish Sea during February 1973. Survey made on ICOT cruise, RS-02-73. Units are pCi l^{-1} . North and south boundaries of the St George's Channel are shown by dashed lines.

of an additional survey⁶ made during May 1972 have also been used in the present study. These analyses were carried out by a method broadly similar to that outlined⁷.

Since the concentrations of ^{137}Cs in the St George's Channel are not at steady state the continuity equation takes the following form

$$\begin{aligned} X_1 U_1 C_{s1} - X_1 K_x \left(\frac{\partial C_s}{\partial x} \right)_1 \\ = X_2 U_2 C_{s2} - X_2 K_x \left(\frac{\partial C_s}{\partial x} \right)_2 + P \end{aligned} \quad (3)$$

where P is the increase in ^{137}Cs within the channel volume during the time period under consideration. This quantity

may be obtained by integration of the ^{137}Cs values, shown in the survey contour charts, over the whole water volume. For this purpose the channel was divided into rectangles $10'$ latitude by $30'$ longitude (604 km^2); each was assigned an equivalent volume based on the mean depth and the fraction of the total area covered by the water. Measurements of the depth distribution of caesium⁸ show that in this region the concentration of caesium does not vary significantly with depth. Consequently in this study the surface value was assumed to apply to the whole water column.

Equations (1), (2) and (3) may be solved for the three unknowns

$$\begin{aligned} K_x = \{ W S_2 C_{s1} - W S_1 C_{s2} + P(S_2 - S_1) \} \left\{ \left(X_2 \left(\frac{\partial C_s}{\partial x} \right)_2 \right. \right. \\ \left. \left. - X_1 \left(\frac{\partial C_s}{\partial x} \right)_1 \right) (S_2 - S_1) - \left(X_2 \left(\frac{\partial S}{\partial x} \right)_2 \right. \right. \\ \left. \left. - X_1 \left(\frac{\partial S}{\partial x} \right)_1 \right) (C_{s2} - C_{s1}) \right\}^{-1} \end{aligned} \quad (4)$$

$$\begin{aligned} U_1 = \left\{ K_x \left(X_2 \left(\frac{\partial S}{\partial x} \right)_2 - X_1 \left(\frac{\partial S}{\partial x} \right)_1 \right) - W S_2 \right\} \\ \cdot \{ X_1 (S_2 - S_1) \}^{-1} \end{aligned} \quad (5)$$

$$U_2 = \{ X_1 U_1 + W \} X_2^{-1} \quad (6)$$

These equations may be evaluated numerically for the time period between each survey using the values given in Table 1 and the information on channel geometry and freshwater flow given in ref. 2. The results, which are given in Table 2, show excellent internal consistency and fall close to the range of values estimated by Bowden.

TABLE 2 Summary of results

Period	K_x $\text{km}^2 \text{ yr}^{-1}$	10^6 cm^2 s^{-1}	U_1 km yr^{-1}	U_2 km yr^{-1}
May to September 1972	8,130	2.59	129	113
September 1972 to February 1973	8,160	2.60	116	103
February to June 1973	8,980	2.86	141	124
Surveys before 1972				
Mean	11,600	3.7	.97	.88
Range	9,500-16,000	2.7-5.1	103-88	91-78

Bowden also considered other sections of the Irish Sea system to the north and south of the present area of study. Attempts to apply the continuity equation for caesium to the most northerly section (the Irish Sea proper) have shown that the assumption of constant K_x leads to anomalous results for this section. This is not surprising in view of the intense and complex mixing and advective processes in the North Channel (see Fig. 1) and the obvious dissimilarities between the north and south boundaries of this section. A further programme of study in this area is being undertaken. South of the St George's Channel (Celtic Sea) the radiocaesium levels are too low for reliable application of the present approach.

It is interesting that the total quantity of ^{137}Cs in the St George's Channel reflects the fact that about one third of the total ^{137}Cs input to the Irish Sea during 1972 was made in the August of that year (H. Howells, personal com-

munication). This 'pulse' apparently arrived at the northern boundary of the St George's Channel at about the time of the survey in February 1973 and shows as a sudden increase in total ^{137}Cs in the results for June 1973. The travel time of 8 to 10 months for passage through the Liverpool Bay system gives an apparent velocity of about 200 km yr^{-1} ; it is possible, however, that the mechanism of transport is predominantly diffusive rather than advective, since tidal mixing is very strong in this region.

In addition to the data used in the above calculations three other, less complete surveys are relevant. These were made as part of the research programme of the Ministry of Agriculture, Fisheries and Food Fisheries Radiobiological Laboratory, Lowestoft. The survey dates are September 1968, December 1969 (ref. 8) and June 1970 (D. F. Jefferies, personal communication). Although none of these surveys includes information on the southern boundary of the St George's Channel it is possible to make estimates of the values in this area from known North Atlantic fallout levels (1.0 to 0.3 pCi l^{-1}) and from the later surveys. This procedure permits the estimation of residual advective velocities and diffusion coefficients for four additional periods between surveys. The range of values of K_z so estimated is given in Table 2. The bias to slightly higher values shown by these estimates when compared with the calculated results may reflect the longer time periods involved, because advective processes operating for periods short relative to the time period concerned cannot be distinguished from diffusive processes and thus tend to increase the apparent diffusion coefficient.

The presence of ^{137}Cs in the Irish Sea system presents a unique opportunity to study large scale advective and diffusive processes over long time and distance scales. The present paper and that of Jefferies *et al.*⁶ illustrate only a few of the ways in which this fortuitous situation can be exploited to improve our knowledge. The near-shore transport processes here investigated control the movement and speed of all natural or artificial materials introduced into the waters around our coasts.

I thank the many people who assisted me with the sampling programme on board RRS John Murray and MV Researcher, and Dr J. P. Riley of the University of Liverpool for the loan of laboratory facilities. Mr H. Howells of British Nuclear Fuels Ltd, Windscale, provided information on the input of ^{137}Cs to the Irish Sea.

An additional location of metalliferous sediments in the Red Sea

INTEREST in Red Sea brines and metalliferous sediments commenced in 1948 with reports of anomalously high bottom water temperatures in the vicinity of Atlantis II Deep¹. These reports were confirmed in the mid 1960s (refs 2-4) and subsequent investigations have revealed at least thirteen occurrences of brine pools and metalliferous sediment throughout the length of the Red Sea⁵⁻⁷. Detailed sampling of one deep, Nereus Deep ($23^\circ 10' \text{N}$, $37^\circ 15' \text{E}$), has indicated the presence of brines and metalliferous sediments of distinctive composition.

Nereus Deep is situated within the NW-SE trending median valley of the Red Sea, is 40 km long by 12 km wide, and is divided along its length by a saddle into two parallel basins (Fig. 1). Each basin contains a number of distinct depressions which either contain brine pools, or show evidence of having contained them in the past. The largest brine pool occurs in the deeper eastern basin filling two of the depressions, which appear to be separated by a low sill (Fig. 1). This brine has a chlorinity of 129.5‰ and a temperature of 30.2°C (ref. 7). In the western basin there is a smaller brine pool, which has a lower salinity, and may be present as a re-

FIG. 1 Bathymetric map of Nereus Deep. Depths of water are in m.

sult of seepage or spillage from the main pool in the eastern basin.

Geochemical analysis of unwashed samples of sediment cores from the Deep has been undertaken for Fe, Mn, Zn, Cu, Pb, Ni, Co, Cr, Hg and Ca using atomic absorption techniques. This has confirmed the observed presence of several metalliferous layers within the sediments.

The most highly metalliferous sediments within the Deep occur in core 70-14 from the south-east slope (Fig. 1) and are apparently unrelated to any existing brine. This core contains four distinct layers of fine grained black-brown sediment of high water content. The true thickness of the deepest of these layers was not determined as the corer stopped within it, but 50 cm of metalliferous material was recovered and the possibility that they formed as a result of the oxidation of these black layers (Table 1) shows Fe to be very enriched, with Mn, Zn, Cu, Pb and Hg also enriched. These layers are chemically most similar to the 'manganite' facies of Chain Deep⁸. Core 496 (Fig. 1) taken from a greater depth in the south-east corner of the deep also contains 3.2 m of iron and manganese rich sediment (Table 1). Below this is at least 1.5 m of Fe-rich sediment.

The origin of the black manganese rich sediments is difficult to explain owing to the absence of any direct connection with existing brine. Possibly they were laid down in association with pre-existing brines, or result from diagenetic remobilization of previously buried manganese dioxide under reducing conditions. Perhaps more likely, however, is the possibilities that they formed as a result of the oxidation of dissolved manganese at the brine/seawater interface, with subsequent precipitation of manganese dioxide around and above the margins of the brine pool (H. Bäckér, personal communication).

Cores such as 486 and 487 from beneath the brine pools in the eastern basin (Fig. 1) show at least four distinct periods of brine influx (Table 1) during which fine banded metal-rich layers were deposited. Examination of the microfossil assemblages of these two cores has shown that the four metalliferous layers can be correlated (S. Ali, personal communication). In core 486 two of these layers are thinner and less metalliferous than the corresponding sediments in core 487, suggesting the sill between these two depressions may have inhibited brine flow from north to south. The brine precipitates have a high salt content and are enriched in Fe, Mn, Zn and Cu (Table 1).

The western basin seems to have had a much shorter history of brine deposition than the eastern basin, brine precipitates only being found in the upper 50 cm of the sediment column below the present brine pool. The salt and metal contents of these precipitates are much lower than in the eastern basin (Table 1), suggesting that the brines in the western basin may have been mixed with normal Red Sea water. The level of initial brine influx coincides with a zinc

and manganese rich layer, containing the maximum values of these elements in core 490 (Table 1).

Major points of interest in Nereus Deep are, therefore, first the occurrence of an appreciable thickness of iron and manganese-rich sediment containing various minor elements and, second, the possibility that, as in Atlantis II Deep^{8,9} sulphide layers rich in zinc, copper and lead may occur at greater depths. Large concentrations of mercury in the Deep (Table 1) support this view and may indicate hydrothermal enrichments of less volatile elements below.

This work was supported by a grant from the Natural Environment Research Council. Ship time was provided by the Directorate General Mineral Resources, Saudi Arabia. We also thank Dr H. Bäckér of Pressaug AG for providing sediment samples and a detailed bathymetric map of the deep.

Crystal formation and growth in bivalve nacre

THERE are two theoretical explanations of the initiation and growth of the tabular aragonite crystals forming the nacreous layer in molluscan shells. The 'template' or 'matrix' hypothesis assumes that crystal nucleation and growth occur on the open surface of conchiolin membranes and may depend on active sites of this organic substratum². This implies a process comparable to epitaxy. In contrast, the 'compartment' hypothesis envisages that nucleation and growth occur within, and are controlled by, pre-existing hollow compartments of the organic deposits³. Two recent

scanning electron microscope (SEM) studies⁴ indicate that in gastropods there are no such compartments at the growth front of the nacreous layer. These studies are, however, not completely conclusive because of insufficient fixation of the samples. We have therefore studied the formation and growth of initial nacreous crystals in several species of bivalves.

We selected young individuals of *Pteria colymbus*, *Isognomon alatus*, *I. radiatus*, *I. bicolor* and *Brachidontes exustus* in which active shell growth was in progress. The molluscs were put in 6% solution of magnesium sulphate in seawater until the tissues were relaxed, then fixed by a 2% solution of glutaraldehyde in cacodylate buffer prepared in seawater for 4 h at room temperature.

After rinsing in buffer, the desired portions of the shells were cut off with the mantles attached. For transmission electron microscopy (TEM), they were dehydrated in an ethanol series, embedded in Spurr⁵ plastics, and sectioned with a diamond knife. Sections were stained with Reynold's lead citrate⁶ and/or uranyl acetate. The uranyl stain also served for decalcification.

For SEM, shells were dehydrated using the critical point method and the mantles pulled off to expose the inner shell surfaces; the samples were then coated with gold-palladium under vacuum.

Observations with the SEM confirmed that, in contrast to gastropods^{4,7} the nacreous layers of these bivalves are formed in a step-like pattern (Fig. 1a), each step corresponding to the growth edge of a nacreous lamina. In front of each lamina appear widely scattered crystals which are in the initial stage of formation. They grow by fast lateral and slower vertical accretion, acquiring first discoidal or sub-hexagonal habits and later fusing into single groups which finally merge to form a coherent nacreous lamina.

Transmission electron microscopy observations of the sections of mantle/shell preparations from semi-mature laminae (laminae crystals of which have not completely fused) reveal a situation similar to that described by Bevelander and Nakahara in other bivalve species⁸. Gaps are often found

between some of the crystals or crystal groups of the latest nacreous lamina. Some of the gaps contain traces of poorly condensed shred-like organic material (Fig. 1b, c). In addition, one or more sheet-like formations of condensed organic material have been observed between the microvilli of the mantle epithelium and the inner face of the nacreous layer. The innermost sheet may correspond to the mucous lining of the microvilli and the other formations may be independent membranous sheets. Examination of larger parts of the inner shell surface with the SEM has shown that such sheets extend over several nacreous steps (Fig. 1a). Thus, in the initial parts of the nacreous laminae these sheets are not strictly parallel to the surfaces of the laminae.

Near the edge of the shell is an organic lining which occupies the junction between the prismatic and the nacreous layer. It extends adorally beyond the growth front of the nacreous layer and covers part of the inner face of the prismatic layer.

The earliest initial stages of nacreous crystals appear on the surface of this lining. In some cases this occurs preferentially in the furrows representing the borders of the underlying prisms (Fig. 1d). A short distance behind they become fused to form the first coherent aragonitic lamina. In some cases the membranous sheets reach far enough forward to cover the growth front of the nacreous layer or even the inner face of the prismatic layer (Fig. 1d).

Our observations have shown that 'compartments' in the functional sense attributed to this term do not exist. In the semi-mature nacreous lamina the gaps covered by the membranous sheet are neither spaces controlling crystal formation and growth nor the result of crystal dissolution⁴ but simply places where the lateral fusion of the nacreous crystals has not been completed. They are certainly not compartments in the sense of the compartment hypothesis. On the other hand, the spaces between two adjacent horizontal membranous sheets as observed by Bevelander and Nakahara could be called compartments if the meaning of this term is restricted to a purely descriptive sense. But it seems questionable whether they control crystal growth.

FIG. 1 Transmission and scanning electron micrographs of growing nacre in bivalves. a, Growing edges of three consecutive nacreous laminae in *Pteria colymbus*, all covered by a membranous sheet removed at the right side. Vertical view. $\times 1,680$. b, Gap in an incompletely fused lower-most nacreous lamina of *P. colymbus*. Vertical section. $\times 35,952$. c, Same. Note the organic envelopes of the crystals and the junction in the intercrystalline conchiolin membrane (arrow). Vertical section, decalcified. $\times 52,248$. d, Growth front of the nacreous layer (upper parts) covering the prismatic layer (lower parts) in *Isognomon alatus*. Note the organic lining underlying the nacre and the membranous sheet covering both layers and removed at right sides. Vertical view. $\times 336$. e, Surface of a growing nacreous lamina in *P. colymbus*. Note the organic envelopes of the crystals and the covering membranous sheet removed in the lower parts. Oblique view. $\times 6,720$. e, organic envelope of nacreous crystals; ic, intercrystalline conchiolin membrane; il, interlamellar conchiolin membrane; mi, microvilli; ms, membranous sheet; ol, organic lining underlying the nacreous layer.

It is true that they contain shreds of organic material in the initial state of consolidation and may, therefore, represent a separate micro-environment enclosing a modified pallial fluid³. Crystal formation and growth, however, seem to be rather independent as each of the initial nacreous crystals has its own organic envelope (e in Fig. 1c) which is independent of the organic sheets of the compartment (Fig. 1e). It is also inconceivable that the invariant vertical distance of the membranous sheet from the surface of the preceding nacreous lamina should be responsible for the uniform thickness of the newly formed mature crystals or lamina. Since this sheet is not consistently parallel to such a surface, its distance is not constant. We, therefore, conclude that the uniform thickness of the nacreous laminae cannot be attributed to the membranous sheet.

According to our observations initial and growing nacreous crystals are covered by a rather "tightly fitting organic envelope"⁴ consisting of one or several very fine linings (Fig. 1c, e) which are somewhat more conspicuous near the base of the crystal (Fig. 1e). During the lateral fusion of the crystals to form a mature nacreous lamina the adjacent lateral portions of the envelopes obviously merge (Fig. 1c) to become Gregoire's "intercrystalline conchiolin membrane". Such fusion of parallel organic membranes of identical structure and composition leaves no traces of a separating boundary. In our case, however, it is implied by the occasional preservation of their junction (arrow in Fig. 1c). The lateral fusion of the upper portions of the crystal envelopes results in the formation of a horizontal organic lamellar complex in which the original separations may remain detectable (arrow in Fig. 1c). This complex and the inner membranous sheet of the compartment forms Gregoire's "interlamellar conchiolin membrane" (see ref. 8).

The tightly fitting envelope of the growing crystals could easily be mistaken for a single membranous sheet belonging to the compartment and draped over the crystals following a collapse of the compartment during the preparation. Such an interpretation is, however, unlikely because the samples have undergone proper fixation and critical point dehydration. Finally it is invalidated by the observation that the envelope extends far under the latero-basal parts of the crystal (Fig. 1c).

There is, of course, the question of how this envelope is able to increase its surface as the crystal within it grows. It is, however, not a rigid structure. Since conchiolin membranes of the nacreous layer represent a network of tiny fibrils (see ref. 8) they can easily be stretched while new fibrils are added to fill the opening meshes. A good model is the avian eggshell membrane which is stretched as the egg grows in the isthmus.

Another question is why the organic envelope does not actually inhibit further growth of the crystal. There is still no answer to this but further investigation may show perforations or permeability of this membrane. Finally, why does the vertical growth of adjacent crystals cease at exactly the same level so that the mineral lamina resulting from their lateral fusion is uniform in thickness?

The evidence presented here shows that the formation and growth of nacreous crystals occur independently of the existence of the compartments from which these crystals are separated by individual tightly fitting organic envelopes. Since this envelope does not delimit a pre-existing space it is not a compartment in the sense of the compartment hypothesis. According to our observations the crystals at the growth front of the nacreous layer are formed on the surface of the organic lining which advances over the inner face of the prismatic layer. At the growth edges of subsequent nacreous laminae such initial crystals are formed on the surface of the interlamellar conchiolin membrane of the preceding nacreous lamina. Thus in both cases crystal nucleation occurs on the surface of an organic substratum,

an observation compatible with the template hypothesis.

Possible cosmic dust origin of terrestrial plutonium-244

THE discovery of ²⁴⁴Pu by Hoffman *et al.*¹ in bastnaesite, a Precambrian rare earth fluorocarbonate ore from the Mountain Pass deposit in California, has raised the question of whether the so-called extinct nuclide, with a half life of 82 m.y., is part of the extant (or almost extinct) nuclide group or whether it was brought to Earth from a cosmic-ray source before the formation of the ore^{1,2}. I have reinvestigated the implications of its present existence in nature in terms of three possibilities: (1) survival of the primeval ²⁴⁴Pu, (2) influx as a heavy cosmic-ray component, and (3) inflow as a cosmic dust component from supernova remnants. The result shows that there are some difficulties with the first two possibilities, both of which were thought to be plausible at the time of the discovery. Although it is still a speculative proposition at present that any part of the cosmic dust falling on the Earth originated outside of the Solar System, a calculation suggests that the ²⁴⁴Pu may have been carried by such dust. The ¹²⁹Xe excess detected by Srinivasan *et al.*³ in an old Australian iodyrite, AgI, is also not inconsistent with the present hypothesis.

The observed amount of ²⁴⁴Pu, 2.0×10^7 atoms, in the 8.5 kg of ore reported in ref. 1 would correspond to an average terrestrial abundance of 2.0×10^{-24} g g⁻¹ or an average crustal abundance of 1.0×10^{-22} g g⁻¹, if the enrichment factor of plutonium was the same as that of cerium during the formation of this ore. The cerium enrichment factor is stated in ref. 1 to be a factor of the order of 5×10^5 greater than its average terrestrial abundance, or about 10^4 greater than its abundance in the Earth's crust. The former value for plutonium concentrations is consistent with an upper limit of 3×10^{-22} g g⁻¹ for the average terrestrial value obtained

earlier by Fields *et al.* from a 1.6 kg gadolinite from the Iveland district of southern Norway⁴.

An amount of 7.8×10^{-27} g ^{244}Pu g⁻¹ is expected for the average terrestrial abundance from the primaevial meteoritic abundance of $[^{244}\text{Pu}/^{238}\text{U}] = 0.013$ (ref. 5) and $[\text{U}] = 2.0 \times 10^{-2}$ p.p.m. (ref. 6 and references cited therein). This expected amount is such that the chemical enrichment of plutonium would have to be about 260 times more than that of cerium, as discussed in a similar way by the original investigators¹. The requirement of this high enrichment of plutonium (1.3×10^3) relative to the cerium enrichment (5×10^5) seems to be difficult to accept in terms of the possibility of a primaevial origin in view of the known chemical similarities between the two elements. Alternatively, the observed concentration may reflect a higher initial abundance of ^{244}Pu at the time of the Earth's formation (4.56×10^9 yr ago) relative to the initial chondritic abundance. A solution to the argument must await a substantiation of the discrepancy by further studies on other samples of bastnaesite.

Price *et al.*⁷ summarised the heavy cosmic-ray track data obtained by balloon flights up to 1971 to be two tracks due to $Z = 96 \pm 2$ per $2,110 \text{ m}^2 \text{ h}$. It may be that an order of one track per $2,110 \text{ m}^2 \text{ h}$ is recorded by ^{244}Pu , which leads to a rate of influx of 5×10^{-33} g ^{244}Pu cm⁻² s⁻¹. Assuming a steady state cosmic-ray source and a factor of survival against nuclear disintegration during passage through the atmosphere of 0.1 (which may be too high), the amount accumulated during the ^{244}Pu mean life (1.2×10^8 yr) results in a concentration of 6.5×10^{-25} g g⁻¹ in the 10 km of the Earth's crust. The assumptions involved are the same as those in ref. 1. But the age of $\geq 5.5 \times 10^8$ yr for the bastnaesite used by Hoffman *et al.* needs to be revised to a more reasonable one of 1.4×10^9 yr in the light of a recent study by Fleischer and Naeser² and the biotite age determined by Lanpher⁸. The expected concentration of ^{244}Pu from cosmic rays is thus reduced to 5×10^{-30} g g⁻¹ in the crust which requires an enrichment factor for plutonium of about 2×10^{11} (20 million times that of cerium in the Earth's crust). A lower influx of cosmic-ray ^{244}Pu and a smaller survival factor for passage through the atmosphere would require a higher enrichment factor for plutonium in this bastnaesite.

The present estimate of cosmic dust influx is around 10^5 tons per year over the entire Earth's surface (S. Tanaka and colleagues, unpublished). The life history of the dust in space is not well known in spite of great concern to many investigators. But a rough estimate using the Poynting-Robertson effect, friction with interplanetary gases, light pressure and gravity as the forces exerted on the dust shows that a dust particle of less than $1 \mu\text{m}$ at 10^4 AU falls down to the Sun within a few thousand million years⁹. Assuming that some of the dust, say 10% of the influx on to the Earth, originated in frequent supernova explosions in our Galaxy and that the dust material is chondritic, with $[^{244}\text{Pu}/^{238}\text{U}] = 0.013$ and $[\text{U}] = 2.0 \times 10^{-2}$ p.p.m., the steady state influx rate of ^{244}Pu is expected to be 1.7×10^{-26} g ^{244}Pu cm⁻² s⁻¹. Using essentially the same assumptions as in the above cosmic-ray calculation, a concentration of 1.6×10^{-22} g ^{244}Pu g⁻¹ in the Earth's crust is deduced. This is almost the same as the average concentration in the crust obtained from the observation of Hoffman *et al.* using an enrichment factor for plutonium equal to that of cerium. The small difference of a factor of 0.6 may be not important, considering the present state of knowledge of ^{244}Pu behaviour from its place of birth to the ore formation, that is, the ^{244}Pu formation in supernovae, its distribution into interstellar medium, the condensation into dust grains, the dust collection efficiency by the Earth, the ^{244}Pu geochemistry and concentration mechanisms and the possible small differences in these properties between plutonium and cerium.

The reported ^{129}Xe excess of $(2.2 \pm 0.2) \times 10^{-12}$

cm³STP/g of natural iodyrite can be ascribed to the *in situ* decay of naturally occurring ^{129}I and leads to iodine with the isotopic composition of $3.3 \times 10^{-15} \geq ^{129}\text{I}/^{127}\text{I} \geq 2.2 \times 10^{-15}$ if extrapolated back to some 50 m.y. ago when the ore was formed³. The concentration of ^{129}I in the Earth's crust is thus expected to be $(1.2 \sim 13) \times 10^{-22}$ g g⁻¹ from the enrichment factor of $(5 \sim 36) \times 10^5$ based on the iodine content of 25% in the ore and the crustal iodine abundance of 0.07 to 0.5 p.p.m. (refs 10, 11).

If the cosmic dust carries 0.1 p.p.m. of iodine with an isotopic composition of $^{129}\text{I}/^{127}\text{I} = 1.1 \times 10^{-4}$ (chondritic values¹²), the global influx rate of 1×10^4 ton yr⁻¹ would correspond to an influx of 7×10^{-28} g ^{129}I cm⁻² s⁻¹ and the same processes mentioned above for ^{244}Pu in the dust would yield a concentration of 2×10^{-19} g ^{129}I g⁻¹ in the crust. This value is two to three orders of magnitude higher than the expected one from the ^{129}Xe observed in the iodyrite.

Iodine is known to concentrate in hydrosphere and biosphere rather than in lithosphere. Even in the crustal materials the iodine contents varies widely from type to type of rocks, for example 0.007 ~ 0.5 (typically 0.046 ~ 0.1) p.p.m. in igneous rocks which are the major crustal rock, 7 ~ 38 (typically 10) p.p.m. in shales which are the major sedimentary rock and 10.9 ~ 49 (typically 50) p.p.m. in deep sea sediments^{11,12}. The variation of iodine concentration between the Earth's surface and deep seated rocks thus ranges over factors of $10^2 \sim 10^4$ which compare reasonably well with the difference of ^{129}I between the expected values from cosmic dust and from the observed ^{129}Xe excess in the iodyrite.

Further contribution of ^{129}I to the Earth's constituents is expected from spontaneous and neutron-induced fission of uranium in rocks^{13,14}, spallation reactions on xenon in the upper atmosphere¹⁵, and neutron and muon reactions on tellurium^{16,17}. An estimate of the additions from these reactions has been obtained by Edwards and his coworkers to be about 2.2×10^{-12} for the marine $^{129}\text{I}/^{127}\text{I}$ ratio, which is within a factor of less than about ten of their experimental values for the Long Beach California brines, ranging from 5×10^{-12} to 2×10^{-11} , for assumed equilibrium ratios with hydrospheric and atmospheric processes at the time of trapping of ^{129}I (ref. 18). These results suggest an incomplete mixing of ^{129}I of the different origins with ^{127}I in various parts of the Earth.

An experimental search for ^{244}Pu in deep sea sediment would be feasible if the present hypothesis is valid. Further studies along this line are under way at our laboratory.

New look at the lead isotope growth curve

THE isotopic composition of lead changes with time due to radiogenic production from isotopes of uranium and thorium. Two lead isotopes are produced from uranium, ^{206}Pb from ^{238}U , and ^{207}Pb from ^{235}U . The paired U-Pb decay schemes are particularly useful since geochronological information can be derived even when there has been a chemical fractionation of U from Pb at some time during the history of the sample. For example, the $^{206}\text{Pb}/^{204}\text{Pb}$ and $^{207}\text{Pb}/^{204}\text{Pb}$ ratios can be measured in a galena (PbS) sample; by assuming that the parent material for the galena had suffered no chemical fractionation of U from Pb from the time of formation of the Earth until production of the galena, one can calculate a 'model' age of formation for the galena. This model is referred to as single stage growth of lead and can be characterised by a μ value [$(^{238}\text{U}/^{204}\text{Pb})$, as measured today] for the parent U-Pb system.

Stanton and Russell¹ suggested that conformable lead ore bodies may be expected to contain lead which would meet the conditions for single stage growth. They found that ores of different ages fitted approximately to a single growth curve and proposed that this curve represented the development of the lead isotopic composition of the lower crust or upper mantle with time. Using high precision analytical techniques Stacey *et al.*² redetermined the single stage growth curve and found that galena samples ranging in age from 0 to 3,100 m.y. fit a curve with $\mu = 9.09 \pm 0.06$.

The calculation of a single stage growth curve depends on a number of variables. First, the parent material for the galena must conform to the requirements of a single, chemically closed U-Pb system. Second, we must know the time at which the U/Pb ratio of the Earth became fixed (commonly referred to as the age of the Earth). Third, we must know the isotopic composition of lead at the time of formation of the Earth and, fourth, we must have accurate values for the decay constants of both uranium isotopes. We will assume for the moment that the first condition is met and look at the effect of the other variables on the calculation of model ages and model μ values.

The geological complexity of the Earth makes a direct measurement of its age of formation impossible. Using lead isotopes Tatsumoto *et al.*³ have measured the ages of several meteorites. The oldest age found was 4.57×10^9 yr (using the new uranium decay constants discussed below). This age is the same as the model lead age for the moon³, and provides the best estimate available for the age of formation of the Earth. Any change in the age of the Earth has the opposite effect to a change in the uranium decay constants since the two terms in the lead isotope growth equations are multiplied together [for example $(^{206}\text{Pb}/^{204}\text{Pb})_t = (^{206}\text{Pb}/^{204}\text{Pb})_{T_0} + \mu (\exp(\lambda T_0) - \exp(\lambda t))$].

The decay constants of uranium were recently determined using modern analytical techniques⁴. The new decay constant for ^{238}U is 0.92% larger than the previously accepted value⁵, whereas that for ^{235}U is 1.28% higher. For directly measured $^{206}\text{Pb}/^{207}\text{Pb}$ ages, such as the meteorite ages discussed above, the effect of the change in decay constants is rather small. At 4,500 m.y. the age difference resulting from recalculation of data with the new constants is -1.4%; at 3,000 m.y., -1.5%; at 1,500 m.y., -1.7% and at 500 m.y., -2.6%. Only at very young ages does the age difference become large. The situation for model ages, however, is quite different. Recalculation of a galena model age using the new decay constants results in a lowering of the model age by 200 m.y. at 3,000 m.y. and 350 m.y. at 600 m.y. model age. Although the largest shift in model age occurs for young samples, the biggest change in model μ values is for old samples. At 3,000 m.y. the newly calculated μ value will be 15% lower than the old value but at 600 m.y. the change is 8%.

Tatsumoto *et al.*³ reported new measurements of Canyon Diablo troilite lead isotopic compositions which are the most primitive yet found. Use of their troilite composition in the model age equation (rather than the values reported by Oversby⁶ results in a decrease in model age of about 100 m.y., regardless of the age of the sample, and lowers the model μ value by 2% for young samples, ranging up to a decrease of 6% for the oldest samples.

The combined effect of replacing all of the previously used physical constants in the model age equations by the more precise new parameters is a large shift in model ages and model μ values for all samples. The oldest samples have their model ages lowered by 300 m.y. (about 9%) and their model μ values decreased by about 20%; for the young samples, the model ages are lowered by 450 m.y. (50%-100%) and the model μ values are decreased by 10%.

Table 1 shows a selection of data from Stacey *et al.*²; the model ages and model μ values were calculated using the new parameters discussed above. Only the two oldest samples have model ages which are in reasonable agreement with the geological age of the surrounding rocks. These samples, which are our best candidates for single stage leads, have quite low model μ values. The youngest samples, whose model ages are about 500 m.y. younger than the age of the surrounding rocks, have considerably higher model μ values. This implies

TABLE 1 Model ages and model μ values for galenas

Locality	Geological age of surrounding rocks (m.y.)	$^{206}\text{Pb}/^{204}\text{Pb}$	$^{207}\text{Pb}/^{204}\text{Pb}$	Model age (m.y.)	Model μ value
Bathurst	460	18.20	15.65	Negative	n.a.

Geneva Lake, Ontario	2,500-2,700	14.00	14.87	2,340	7.89
Manitouwadge	2,700	13.21	14.40	2,630	7.39
Barberton	3,100	12.46	14.08	3,080	7.56

Isotopic composition data and ages of surrounding rocks from Stacey *et al.*². Constants used in model age calculation: $T_0 = 4570$ m.y.; uranium decay constants from Jaffey *et al.*⁴, $^{238}\text{U} = 0.155125 \times 10^{-9} \text{ yr}^{-1}$, $^{235}\text{U} = 0.98485 \times 10^{-9} \text{ yr}^{-1}$; initial lead isotopic composition³, $^{206}\text{Pb}/^{204}\text{Pb} = 9.307$, $^{207}\text{Pb}/^{204}\text{Pb} = 10.294$.

Fig. 1 Lead isotopic growth curves for $\mu = 7.8$ (a) and $\mu = 8.1$ (b), with isochrons for 2,500 m.y. (A), 1,000 m.y. (B) and 0 m.y. (C). The galena data from Table 1 are plotted, together with data from Sullivan, British Columbia, South-west Finland, and Cobalt, Ontario. See Russell¹⁰ for references to the original data. The trend line for recent volcanic rocks¹⁰ is shown for comparison.

that the source region for conformable galena deposits has experienced an increase in its U/Pb ratio at some time between 2,600 m.y. and 1,600 m.y. The data are plotted together with a few additional analyses in Fig. 1. Single stage growth curves for μ values of 7.8 and 8.1 are shown for reference. The general trend of the data suggests a parent system which has had a small, rather steady increase in U/Pb ratio with time. This may reflect an increasing component of lead from upper crustal sources in the younger galena deposits, or may represent evolution of the lower crust and upper mantle.

Two apparent paradoxes associated with the single stage growth curve have disappeared by using the new decay constants. Several authors have argued that the age of the Earth must be considerably greater than 4,550 m.y. since old galena and feldspar samples contained lead whose model age was older than the geological age of the specimen^{7,8,9}. Using the most recent decay constants and initial lead composition for the Earth produces no cases in which model lead ages are older than the geological age of the samples, when either 4,550 m.y. or 4,570 m.y. is used for the age of the Earth.

The second apparent paradox concerned the comparison of lead isotope data from recent volcanic rocks with the galena model growth curve. Russell¹⁰ discussed the problem in detail and constructed a mixing model to try to resolve the paradox. Figure 1 shows the trend line for recent volcanic rock leads in relation to the galena growth curve. Using the old decay constants to construct the growth curve produced an intersection of the trend line with the geochron ($t = 0$ isochron), which fell at a much lower model μ value than that of the galena growth curve. Thus, one had to postulate a rather different history for the source regions of the volcanic rocks and the galena deposits. Use of the new decay constants produces an intersection of the volcanic trend line with the geochron at a model μ value of about 7.9. The volcanic data are better represented by a band of constant width with the same slope as the trend line. This band would intersect the geochron at model μ values of 7.8 and 8.0, very close to the range in model μ values indicated by the galenas. We may therefore postulate that the source regions of the volcanic rocks and the galenas have had similar histories in terms of their lead isotopic development, although the highest model μ values for the youngest galenas might suggest that the fractionation of U and Pb in the galena source regions either began earlier, or was somewhat more intense than the fractionation in the source regions for the volcanic rocks.

Considering the rather drastic changes brought about by the use of the new decay constants and initial lead isotopic composition, it is perhaps prudent to consider the error limits

on the present set of parameters used in model age calculations. The main chance of error in the initial lead isotopic composition would be if the troilite nodule analysed by Tatsumoto *et al.*³ contained a small amount of radiogenic lead as well as primordial lead. Lowering the initial $^{206}\text{Pb}/^{204}\text{Pb}$ from 9.307 to 9.214, and the $^{207}\text{Pb}/^{204}\text{Pb}$ from 10.294 to 10.236 would result in a change in model age of only 13 m.y. It is extremely unlikely that the initial lead composition was as low as these hypothetical values. It is possible that the age of the Earth might be slightly greater than the value of 4,570 m.y. used in the calculations above—although there is no positive evidence that the Earth is older than the Moon and meteorites. If we increase the age of the Earth to 4,600 m.y., the Barberton model age is lowered by 40 m.y. to become 3,040 m.y. and the Balmat model age is lowered by 125 m.y. to 460 m.y. The uncertainty in the decay constants of uranium is claimed to be less than 0.1% (ref. 4). This introduces an uncertainty of ± 7 m.y. in the model age of the oldest samples and ± 20 m.y. in the youngest model ages. There seems to be no likely source of error which would lead to a significant bias towards young ages among the model ages calculated with the new parameters. Pending availability of more data on meteorite ages, it is suggested that uncertainties in the model ages of old samples be assigned at between +10 and -40 m.y. and for young samples at between +20 and -125 m.y.

Post-Cretaceous faulting in Sudan and its relationship to the East African Rift system

It has been widely believed that no relatively young faulting has taken place in Sudan since the Mesozoic. The national Geological Map of Sudan, scale 1:4 million, 1963 edition, and the International Tectonic Map of Africa, scale 1:5 million, 1968 edition, show no faults in the territory and indeed the most recent comprehensive reviews of the structure of Sudan^{1,2} indicate that the late Phanerozoic formations are not significantly affected by faults.

In northern Sudan the Nubian Sandstone Formation is the most extensive of the Phanerozoic strata. It is of Cretaceous age and comprises basal conglomerates, thick cross-bedded sandstones and mudstones. It has been stated¹ that no major faults affect this formation but that minor fractures with a displacement of only a few feet occur near Wadi Halfa and that minor faults affect sedimentary strata in the Red Sea Hills in the east of the country.

Recent geological mapping, geophysical investigations, and aerial photography and satellite imagery in various places across central and northern Sudan have indicated considerable faulting with significant downthrows. The faults can be recognised on the ground by stratigraphic dislocation, brecciation, iron mineralisation and silicification. The latter is highly developed along joint planes in the Nubian sandstones and both may be genetically related.

Evidence of faulting of the Nubian Sandstone Formation has been observed at several localities (Fig. 1), which can be summarised as follows.

(1) South of Khartoum. Along the White Nile valley older E-W and younger N-S to NNW faults with downthrows normally to E and NE occur, and at Jebel Aulia a NNW-trending fault has a displacement of more than 1,200 m^{3,4}. The partial effect of faulting and warping has been the Gezira depression, in which buried Nubian Sandstone Formation is preserved beneath Tertiary to Pleistocene sediments (Gezira Formation) up to 110 m thick.

(2) North of Khartoum. The sedimentary cover to the Sabaloka basement inlier is displaced by E-W and N-S faults^{5,6}, with probable rejuvenation along earlier planes of weakness in the basement.

(3) Central Sudan, Kordofan Province. At Bara village (Fig. 1) a NW-SE trough was revealed by gravity measurements and drilling^{7,8}. The depression is 50 km wide, at least 150 km long, and more than 400 m deep. It is filled with Nubian Sandstone Formation and Tertiary to younger fluvial sediments (Umm Ruwaba Formation; compare Gezira Formation).

(4) En Nahud to Fula, Kordofan Province. Geophysical work⁹ supported by drilling revealed faulted Nubian Sandstone Formation troughs trending NNW at Fula and probably forming a large NW-SE basin beneath Babanusa. Along the south edge of the sediment-filled Nahud outlier¹⁰ E-W faulting was indicated.

(5) Western Sudan, Darfur Province. Fault-controlled NW-SE depressions¹¹ near El Fasher (Fig. 1) contain more than 1,200 m of Nubian Sandstone Formation. Near Zalingei a broad zone of fractures displacing basement gneisses and lower Palaeozoic strata strikes NNW to NW and is associated with Tertiary to Recent volcanism¹². The zone is covered by recent sediments south of Babanusa.

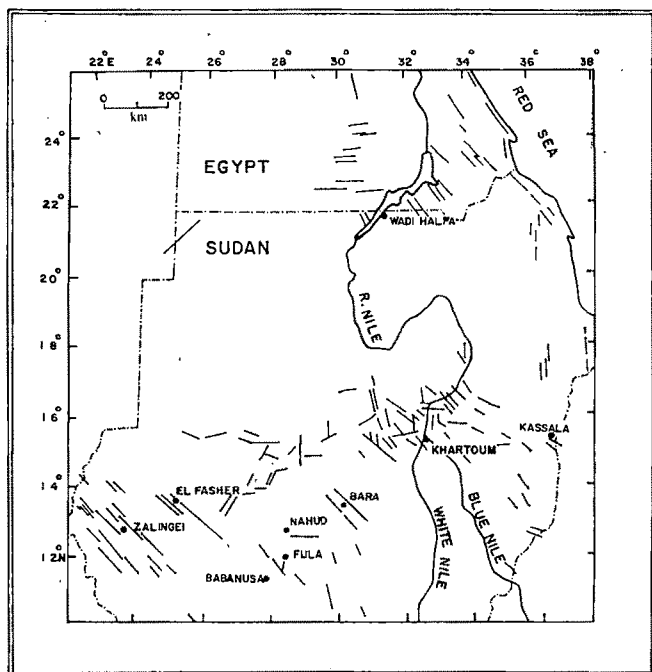

FIG. 1 Sketch map to show the distribution of post-Cretaceous faulting in Sudan and southern Egypt. Modified after Said¹⁸ and Vail²⁶.

(6) Eastern Sudan, Kassala Province. Faults displacing Nubian Sandstone Formation type sediments, the Gedaref Sandstone¹ and Tertiary basalts are recorded¹⁸⁻¹⁶ with general NW and NNE trends and with downthrows of up to 120 m.

(7) Northern Sudan and southern Egypt. Near Wadi Halfa faults trend E-W, NW or NNE¹⁷⁻²⁰. In Egypt faults trending N-S and NNW extend over 20 km with displacements up to 50 m (ref. 17). West of the Nile (Fig. 1) major faults cut Nubian Sandstone Formation and Upper Cretaceous strata; displacements are unknown.

(8) Red Sea coast. Tertiary sedimentary rocks along the coastal strip are affected by NNW, ENE and N-S faults^{18,21} with downthrow usually exceeding 50 m; total displacements may be considerable. Inland, faulting is difficult to recognise in the basement but satellite imagery indicates N-S to NW fracture patterns parallel to the Red Sea coast.

The age of the faulting may be indicated from the rocks affected. Across most of the northern half of Sudan the faults cut the Nubian Sandstone Formation of Cretaceous age, whereas in parts of eastern and western Sudan the faults displace Tertiary basalts. In southern Egypt E-W faults displace Nubian, Upper Cretaceous and lower Tertiary strata¹⁸. It may be assumed that most of the movement occurred during early Tertiary to more recent times. In Kordofan Province, for example, igneous activity of alkaline and carbonatitic character²² is apparently related to a fracture zone in which the most recent movement was only a few years ago²³.

The relationship between the post-Nubian faulting in the Sudan and the East African rift system is not known at present. The Egyptian geologists^{17,18,24} tend to consider a number of troughs or rifts to be present; however, there is some doubt whether these fractures can be directly related to rift valley tectonics²⁵ as has been claimed^{19,24}. Several of the fault depressions such as those at Jebel Aulia (just south of Khartoum), Bara and El Fasher are of the same order of magnitude as parts of the rift valleys of East Africa, and some have compatible trends. Several have been postulated as being structural features of the East African system^{7,18,19,24}. Unlike the East African rifts, however, the surface expression in Sudan is negligible, the grabens being for the most part filled by more recent sedimentary deposits, and buried beneath a superficial cover. The faulting has been assumed to have been mainly of Tertiary or Quaternary age and in this respect it is comparable to the main periods of rift faulting during the Miocene further to the south.

It seems therefore that the post-Nubian faulting in Sudan is broadly contemporaneous with the East African rift system, although morphologically not so evident at the surface, and that it probably resulted from related tectonic activity and associated volcanism that produced the East African system. Until more detailed mapping has been done, however, these fractures in Sudan should certainly not be referred to as rift valleys.

BIOLOGICAL SCIENCES

5-Hydroxytryptamine accumulation in cerebrovascular injury

SEVERAL reports¹⁻³ indicate that some biogenic amines may significantly affect the intensity of the brain tissue reaction to injury, and that 5-hydroxytryptamine may be an essential factor in the production of brain oedema. This study was undertaken to explore this possibility, using as an experimental model brain oedema produced by the application of a cold metal plate to the exposed cerebral cortex of the cat⁴. This procedure results in severe damage to the upper cortical layers, including the disruption of blood vessels and the development of a vasogenic type of oedema. Vasogenic oedema is characterised by extracellular oedema fluid, containing extravasated serum constituents, spreading preferentially through the underlying and adjacent white matter⁵. It has been shown that the leakage of serum constituents is confined to the site of cortical injury, and that vascular permeability in the area of oedematous white matter itself, as tested for by protein tracers, remains unchanged⁶.

In the course of our investigations, we discovered that 5-hydroxytryptamine accumulates to a striking degree in the blood vessels in the region of cortical injury, although the oedematous white matter itself does not show any appreciable change in its 5-hydroxytryptamine levels. Here we describe this previously undescribed manifestation of nervous tissue reaction to severe injury.

Cold lesions were produced in cats by a procedure described previously⁴, and the animals were killed after 6 h. Corionally sectioned blocks of the brain, 2 mm in thickness and each containing the area of cold injury and adjacent gyri, were subjected to freeze-drying and processing according to the Falck technique⁷. Under the fluorescence microscope, the blood vessels within the area of cold injury showed a bright, yellowish-green fluorescence. Fluorescence of this nature was conspicuous in the walls of arteries, veins, and capillaries (Fig. 1). A few blood vessels showed an irregular, 'mottled' pattern of yellowish-green fluorescence in their lumina. Otherwise, the thrombotic material filling numerous blood vessels revealed only a faint bluish autofluorescence.

FIG. 1 Area of cortical cold injury, with blood vessels exhibiting a bright, yellowish-green fluorescence in their walls.

The characteristic yellowish-green fluorescence was not observed either in brain tissue adjacent to the fluorescent vessels or in blood vessels outside of the region of injury.

Microspectrofluorometry of the yellowish-green fluorescent vessels in the tissue sections revealed that this fluorescence had the excitation-emission spectra and photodecomposition rate characteristic of 5-hydroxytryptamine (Fig. 2).

The area of cortical cold injury and the underlying oedematous white matter were assayed for 5-hydroxytryptamine using a modification of the method of Maickel, *et al.*⁸ 5-Hydroxytryptamine in the injured cortical region was $329 \pm 30\%$ (mean \pm s.e.m.) of that in the contralateral uninjured cortex; that in the underlying oedematous white matter remained at control levels.

Platelets seemed to be a potential source for the 5-hydroxytryptamine accumulating in the blood vessels. We tested this hypothesis by labelling platelet 5-hydroxytryptamine, producing cold lesions, and measuring the specific activity of 5-hydroxytryptamine in control and injured brain areas.

Whole cat blood (10 ml preserved with USP Formula A citrate dextrose) was incubated with ³H-5-hydroxytryptamine creatinine sulphate (specific activity 7.3 Ci mmole⁻¹), in a final concentration of 1.37×10^{-6} M, for 30 min at 37° C. Labelled blood was re-injected into the cat, and a lesion was made. Tissue 5-hydroxytryptamine was extracted into butanol and acidified heptane, after Maickel, *et al.*⁸ and counted by liquid scintillation. 5-Hydroxytryptamine in the injured cortex had a specific activity 1500% of that in the control cortex and of that in both oedematous and control white matter.

After intravenous injection of 100 μ Ci of ³H-5-hydroxytryptamine binosalate (specific activity 1.0 Ci mmole⁻¹), 5-hydroxytryptamine in the injured cortical region had a specific activity 800% of that in control cortex, oedematous white matter, and control white matter.

The data suggest that a major portion of the 5-hydroxytryptamine accumulating in the area of the cold lesion is contributed by platelets. In addition, preliminary observations on cortical cold lesions in other species indicate a correlation between platelet 5-hydroxytryptamine content and the presence of fluorescent vessels. Species known to have appreciable quantities of 5-hydroxytryptamine in their platelets, such as rabbit, exhibit fluorescent vessels in the area of injury; species whose platelets contain little 5-hydroxytryptamine, such as the rat, show no fluorescence of vessels.

FIG. 2 Excitation (EX) and emission (EM) spectra of a fluorescent blood vessel (—), and of a 5-hydroxytryptamine oxalate sample (---) dissolved in buffered 1% gelatin at a concentration of 1 mg ml⁻¹. Microspectrofluorometry was carried out using a modified Leitz fluorescence microspectrophotograph. A quartz optical system was utilised for obtaining excitation spectra¹².

The exact structural localisation of the 5-hydroxytryptamine observed in blood vessels remains uncertain because of the limited resolution of the light microscope. The lack of fluorescent material in the lumina of many fluorescent vessels suggests that platelets entrapped in luminal thrombi have released their endogenous 5-hydroxytryptamine. In this context, it has been shown that platelet 5-hydroxytryptamine is rapidly released during thrombus formation^{9,10}. It seemed, in some instances, as if 5-hydroxytryptamine was localised in the endothelial lining or muscular coat of the vessels. Presumably, it is sequestered cytoplasmically in such a manner that it is not degraded rapidly by mitochondrial monoamine oxidase.

The significance of 5-hydroxytryptamine accumulation in injured blood vessels remains to be ascertained. It is possible that this phenomenon may occur in vascular injuries other than those produced by cold, probably in those associated with thrombus formation. The possibility that 5-hydroxytryptamine acting on cerebral blood vessels may affect their permeability is supported by the recent observation of Westergaard and Brightman¹¹ that 5-hydroxytryptamine and other biogenic amines reaching arterioles and venules from the brain parenchyma may alter their permeability to protein tracers. It is conceivable that the presence of appreciable amounts of 5-hydroxytryptamine in injured blood vessels may significantly affect the duration and intensity of vascular leakage, which is a crucial factor in the dynamics of vasogenic brain oedema.

We thank Dennis L. Murphy of the National Institute of Mental Health for assistance in the labelling of the platelets.

Ascorbic acid and biological alkylating agents

THE dangers to health from nitrite in the environment generally, and its use in meat processing in particular, have been pointed out by several groups¹⁻³. These dangers are associated with the production of nitrous acid in the acid environment of the stomach and the further reaction of this substance with naturally occurring and synthetic secondary and tertiary amines to form nitroso compounds which may be carcinogenic, mutagenic and cytotoxic. Ascorbic acid has been shown to effectively compete with amines for nitrous acid *in vitro*⁴ and it has been suggested that co-administration of ascorbic acid with potentially nitrosatable drugs, and foods containing nitrite, may reduce the hazards associated with ingestion of these substances⁴.

Kamm *et al.*⁵ have recently demonstrated the protective effect of ascorbic acid on the hepatotoxicity resulting from dual administration of sodium nitrite and aminopyrine to rats. Hepatotoxicity in this case is believed to be due to the formation of dimethylnitrosamine by reaction of nitrous acid with aminopyrine. They also reported⁵ that administration of sodium ascorbate, together with an oral dose of dimethylnitrosamine, partially prevented the liver damage produced by dimethylnitrosamine alone, thereby demonstrating an ascorbate-mediated protection which does not involve competition for nitrous acid. I wish to suggest a mechanism for the latter protective effect which may have general importance in the detoxification of environmental alkylating agents and in explaining certain aspects of their biological effects.

Many carcinogens, including dimethylnitrosamine, are believed to function as alkylating agents. They are either alkylating agents *per se* or they are metabolically converted into alkylating agents. A little-appreciated chemical property of ascorbic is its ability to react with alkylating agents⁶⁻⁹. At physiological pH, ascorbic acid (*pK*_a, 4.2) is largely in the anion form (I) and it is therefore particularly susceptible to alkylation *in vivo*¹⁰. The formation of ascorbigen (II) in plants¹¹⁻¹³ clearly illustrates the reactivity of ascorbic acid towards alkylating agents. Formation of ascorbigen involves alkylation of the ascorbic acid anion (I) by indole-3-methanol (III)⁸. This occurs very rapidly following the formation of indole-3-methanol in certain plant tissues in response to injury.

Under physiological conditions alkylation of the ascorbic acid anion (I) will occur mainly at C₂ of the ambident nucleophile to produce a new carbon-carbon bond, rather

(I)

(II)

(III)

than at the alternative oxygen site^{6,7} (compare ascorbigen). The carbon-carbon bond formed, unlike the carbon-oxygen bonds normally produced by the reaction of alkylating agents with other types of acid groups found *in vivo*, such as, carboxylic and phosphoric acids, will not be particularly susceptible to hydrolytic cleavage. Alkylation of ascorbic acid will therefore effectively compete with the alkylation of other cellular nucleophilic sites such as those on nucleic acids and proteins. It is this competition which I believe may provide a mechanism for the observed protective effect of sodium ascorbate on the hepatotoxicity of dimethylnitrosamine.

Ascorbic acid, if present in sufficient concentration, may also afford protection from the adverse effects of a number of other environmental alkylating agents by the same mechanism and the maintenance of high tissue levels of ascorbic acid may be of value for this reason. Some animal species, unlike man, are capable of synthesising ascorbic acid and this synthetic capacity, besides supplying the basic ascorbic acid requirement, may constitute a part of the metabolic defences of these animals. Thus a number of chemicals, including the carcinogenic hydrocarbons, 3,4-benzpyrene and 3-methylcholanthrene, are powerful stimulators of ascorbic acid synthesis in several animal species^{14,15}. The same chemicals are also potent stimulators of certain drug-metabolising enzymes in the liver¹⁵. Whereas the action of these enzymes detoxifies many harmful compounds, in some instances they convert chemicals to more toxic alkylating derivatives. The stimulation of ascorbic acid biosynthesis which accompanies the increase in activity of the drug-metabolising system may therefore represent an adaptation which, by providing a means of inactivating the alkylating metabolites produced by the drug-metabolising enzymes, would be of considerable benefit to the animal.

A extension of the above suggestion is that some of the biological effects of alkylating agents, which have in the past been mainly associated with their ability to alkylate nucleophilic sites on nucleic acids and proteins, may stem from the alkylation and rapid depletion of cellular ascorbic acid. It has been reported¹⁰ that a common feature of a number of carcinogens is their ability to degranulate the rough endoplasmic reticulum of cells¹⁶. Ascorbic acid deficiency in the fibroblasts of guinea pigs is characterised by a marked reduction in the extent of the rough endoplasmic reticulum, an increase in the number of free ribosomes and disorientation of the ribosomes which remain attached to the membrane^{17,18}. These abnormalities are reversed by

treatment with ascorbic acid, early changes being observed four hours after treatment with ascorbic acid and a return to an essentially normal state after 24 h^{17,18}. Thus ascorbic acid appears to be important for the normal attachment of polyribosomes to the endoplasmic reticulum and the degranulation of the rough endoplasmic reticulum associated with the action of carcinogens may, at least in some cases, be symptomatic of a rapid depletion of ascorbic acid.

Existing evidence supports the view that carcinogens will deplete animals of ascorbic acid. Smoking is reported to lead to a significant loss of ascorbic acid¹⁹. The carcinogen benzanthrone is known to markedly deplete guinea pigs of ascorbic acid²⁰ and some of the symptoms of benzanthrone toxicity have been successfully treated with ascorbic acid^{20,21}. Carbon tetrachloride, another carcinogen which is believed to act through a radical intermediate and which is known to degranulate the rough endoplasmic reticulum of hepatocytes¹⁶, provokes a marked depletion of ascorbic acid in the liver of rats²². Ross and Benditt¹⁷ have remarked on the similarity in appearance of the scorbutic fibroblast and the carbon tetrachloride damaged hepatocyte and ascorbic acid is reported to strongly protect guinea pig hepatocytes from carbon tetrachloride damage²³ suggesting that a rapid depletion of cellular ascorbic acid may play an important part in carbon tetrachloride toxicity.

There can be little doubt that a rapid depletion of cellular ascorbic acid will have an adverse effect on a number of cellular processes. The possibility that biological alkylating agents and some other chemicals such as carbon tetrachloride may be capable of this action should therefore be more widely known.

Possible involvement of cyclic GMP in growth control of cultured mouse cells

NON-TRANSFORMED fibroblastic cells in tissue culture exist in one of two reversible growth states, a state of rapid proliferation (growing) and a state of relative quiescence (resting)^{1,2}. Transition from a resting to a growing state can be accomplished by a variety of mitogenic agents including growth substances in animal sera, insulin and proteases. 3', 5'-cyclic adenosine monophosphate (cyclic AMP) was implicated in this transition^{3,4} in that the intracellular concentrations of cyclic AMP in resting cell cultures fall after brief exposure to mitogenic agents^{3,4} and exogenous additions of high concentrations (10^{-4} to 10^{-3} M) of dibutyryl cyclic AMP to the culture medium cause a partial reversal of the mitogenic response⁵. Kram and Tomkins⁶ have shown that exogenous additions of 3', 5'-cyclic guanosine monophosphate (cyclic GMP) to the medium of cultured mouse cells can counteract the inhibitory effects of dibutyryl cyclic AMP upon some of the earliest events induced by a mitogenic signal (increased uptake of uridine, leucine, and 2-deoxyglucose). We now report (1) that relatively high concentrations (10^{-6} to 10^{-4} M) of cyclic GMP or its butyrate analogues when added to quiescent Balb/c 3T3 cultures can induce a substantial increase in DNA synthesis and (2) that within a few minutes of serum addition to quiescent cultures the intracellular concentration of cyclic GMP, as measured by two independent methods, rises by a factor of nine- to eleven-fold. Cyclic AMP and cyclic GMP concentrations were also measured throughout the remainder of the cell cycle.

Balb/c 3T3 cells obtained from Dr S. Aaronson were routinely grown in 10 ml of Dulbecco's modified Eagles medium (DEM) with 10% calf serum (Colorado Company) in 9 cm Petri dishes at 37°C under a 10% CO₂ (v/v) atmosphere⁷. For determinations of the intracellular concentrations of cyclic nucleotides monolayer cultures were quickly washed with Tris-buffered saline, 1 ml of 5% trichloroacetic acid (TCA) added per dish, and the contents immediately frozen on dry ice. Cultures were then stored frozen. Samples were thawed and centrifuged and the supernatant was extracted with ether and lyophilised to dryness⁸. The combined dry residues of ten Petridish cultures (1.5×10^7 to 2×10^7 cells) were dissolved in 1.5 ml of 0.1 M Tris-HCl (pH 8.5), 0.005 M MgCl₂ and half the samples were digested with 10 μ g ml⁻¹ 3', 5'-cyclic nucleotide phosphodiesterase to check the authenticity of the products assayed³. Both phosphodiesterase-treated and untreated samples were applied to 2 ml Dowex columns (Biorad AG 1-X8, 200-400 mesh, formate form) and the cyclic AMP- and cyclic GMP-containing fractions eluted by 2 N and 5 N formic acid respectively. Solutions were lyophilised to dryness and redissolved in 0.05 M

sodium acetate at either pH 4.0 or pH 6.2 for cyclic AMP- or cyclic GMP-containing fractions respectively. ³H-cyclic AMP and ³H-cyclic GMP were added after the initial thaw-

FIG. 1 Serum-induced sequential changes in cyclic nucleotide concentrations. *a*, Intracellular amounts of cyclic AMP⁹ (○) and cyclic GMP¹⁰ (●) were measured at different times after 20% serum and fresh medium addition to resting cultures of Balb/c 3T3 cells. Cell cultures were used 4 d after termination of DNA synthesis (less than 0.6% of the nuclei were labelled with ³H-thymidine in 18 h), and ten Petri dish cultures were isolated for each determination as described earlier. Similar results were observed if the Tris-buffered saline washing of the monolayer cultures was omitted. All results were corrected for differential losses during the isolation procedures (see earlier) and are expressed in pmol per 10⁶ cells. Duplicate results agreed to within 10%. Results after 3',5'-cyclic nucleotide phosphodiesterase digestion³ have been subtracted (0.1 and 0.3 pmol per 10⁶ cells for cyclic AMP and cyclic GMP respectively). Packed cell volumes and protein content per cell measured under these conditions do not vary more than 10% to 20% with changes in the cellular growth state¹², and thus the amounts measured reflect the relative intracellular concentrations. In the assays cyclic nucleotide amounts were measured in the range 0.1 to 1 pmol, and there was less than 1 part in 10,000 cross interference of cyclic AMP with the cyclic GMP radioimmuno assay. *b*, Parallel cultures were also radioactively labelled with 3 μ Ci ml⁻¹ ³H-thymidine at 3 μ M for 2 h and the c.p.m. of ³H-thymidine incorporated into DNA (Table 1) recorded for a fifth of the cultures; the time-point represents the midpoint of the 2 h pulse-label (▲). Other cultures were also continuously labelled with 3 μ Ci ml⁻¹ ³H-thymidine at 1 μ M from 5 h after medium change until the time recorded for isolation (□) and then processed for autoradiography⁷. The fraction of cells with radioactively labelled nuclei was recorded (□). Cell numbers per 9 cm Petri dish were estimated in a Coulter Counter as previously described¹² (Δ).

Results are expressed in thousands of c.p.m. of ³H-thymidine incorporated into DNA minus the value for control cultures with no additions (3,100 c.p.m.). Duplicate results agreed to within 15%. Abbreviations: DB, dibutyryl; MB, monobutyryl. Balb/c 3T3 cells were seeded in 5 cm Petri dishes at 10⁶ cells per dish in 5 ml of DEM medium containing 2% calf serum (v/v). Seven days later the medium was removed, cell monolayers washed twice with DEM alone, and fresh media containing 250 μ g ml⁻¹ bovine serum albumin, 0.5 μ g ml⁻¹ hydrocortisone (Calbiochem), and 0.1 ng ml⁻¹ of a purified pituitary growth factor¹¹ were added. After two further days (cell density 1.5×10^6 per dish) the various nucleotides (from Sigma and Boehringer) were added, and the cell cultures were radioactively labelled with 3 μ Ci ml⁻¹ methyl-³H-thymidine at 3 μ M from 12 to 30 h after nucleotide additions. Medium was then removed, cell monolayers washed twice with Tris-buffered saline and lysed with 2.0 ml of 0.5 N NaOH. One millilitre of the cell suspension was incubated 16 h at 37°C before the DNA was precipitated with 10% TCA and 50 μ g carrier calf thymus DNA. Precipitates were collected on glass-fibre filters and analysed for radioactivity¹². Addition of 20% calf serum yielded 112,000 c.p.m. of ³H-thymidine incorporated into DNA. Autoradiography⁷ of parallel cultures showed that approximately 1%, 15%, 18%, and 85% of the cell nuclei became radioactively labelled with ³H-thymidine after no addition, or the addition of 25 μ M DB cyclic GMP, 25 μ M MB cyclic GMP, or 20% serum respectively.

TABLE 2 Relative intracellular amounts of ^{32}P -cyclic nucleotides

	Resting cells	Serum-activated cells	Ratio: (Activated cells)/(Resting cells)
^{32}P -cyclic AMP (c.p.m.)	2,960	1,160	0.39
^{32}P -cyclic GMP (c.p.m.)	6,850	63,000	9.2
Labelled Nuclei (%)	0.8	83	100
DNA Synthesis (c.p.m.)	980	97,300	99

Forty Petri dishes (9 cm) of resting Balb/c 3T3 cells in DEM (2×10^4 cells per dish) were radioactively labelled with $100 \mu\text{Ci ml}^{-1}$ ^{32}P - H_2PO_4 for 11 h. Fresh medium containing 20% serum and $100 \mu\text{Ci ml}^{-1}$ ^{32}P - H_2PO_4 were added to twenty dishes (serum activated cultures) and all cells were isolated 19 min later as described. ^3H -cyclic AMP and ^3H -cyclic GMP were added to standardise the recovery and to act as reference markers. Approximately 1.5×10^4 c.p.m. of ^{32}P -TCA-soluble material was recovered in each case. After lyophilisation following ether extraction the dry residues were dissolved in 0.5 N HCl and chromatographed over successive cationic³ and anionic (Fig. 1) Dowex columns to remove ^{32}P - H_2PO_4 and nucleotide di- and triphosphates. Cyclic AMP- and cyclic GMP-containing fractions (Fig. 1) were lyophilised and dissolved in 0.1 M ammonium acetate (pH 7.0). Samples were applied to Whatman 3 MM paper and the chromatogram developed in a solvent of 3.5 parts of butanol, 2.5 of acetone, 4 of 0.5 M ammonium acetate (pH 7.5) for 38 h. The chromatogram was cut into 0.5 cm strips and analysed for radioactivity; the ^{32}P -cyclic nucleotides were well separated from other nucleotides (distances from origin: cyclic AMP, 40 cm; cyclic GMP, 33.8 cm; deoxy-TMP, 27.2 cm; AMP, 18.4 cm), and comigrated exactly with the ^3H -markers. ^{32}P -c.p.m. in the cyclic nucleotide regions were recorded for duplicate experiments which agreed to within 15%. Total cyclic nucleotide ^{32}P -c.p.m. were corrected both for losses in handling (approximately 50% of the ^3H markers were recovered) and for ^{32}P radioactive decay. Counts per minute of ^{32}P -ATP (or GTP) isolated from either resting or 20 min serum-stimulated cells were approximately the same, and thus the intracellular specific activity of ATP (or GTP) was constant. Comparison of ^{32}P c.p.m. of cyclic AMP and cyclic GMP do not reflect their relative concentrations in the cell as the intracellular specific activities of their precursor molecules (ATP, GTP) are different for a 12 h labelling period¹². Parallel cell cultures were also radioactively labelled with $3 \mu\text{Ci ml}^{-1}$ ^3H -thymidine at $3 \mu\text{M}$ from 14 to 28 h after medium change and the cultures isolated for autoradiography⁷ or DNA synthesis analysis (Table 1). Results are expressed as the fraction of cells with radioactively labelled nuclei (%) or as the c.p.m. of ^3H -thymidine incorporated into DNA for a tenth of one Petri dish culture.

ing of the cultures to monitor recovery, usually 70% to 80% of the input was recovered with less than 10% cross contamination in the respective cyclic nucleotide fractions. Cyclic AMP was measured by the protein kinase binding assay of Gilman⁹, and cyclic GMP by the radioimmune assay of Steiner *et al.*¹⁰.

Balb/c 3T3 cells could be maintained in a resting state in the absence of exogenously added serum by addition of very low concentrations of a growth factor purified from bovine pituitary glands¹¹ (less than 1% of the cellular nuclei became radioactively labelled with ^3H -thymidine in 18 h). Various nucleotides and their butyrate analogues were then added and Table 1 shows the changes observed in the incorporation of ^3H -thymidine into DNA. Only 3', 5' cyclic GMP and its butyrate analogues together with monobutyryl cyclic inosine monophosphate (cyclic IMP) yielded a substantial induction of DNA synthesis (eight to ten times the value in resting cultures); other nucleotides tested including cyclic AMP and 2', 3' cyclic GMP failed to do so. Results obtained exactly as described in Table 1 on addition of 250 μM monobutyryl cyclic GMP; cyclic GMP; GMP; or no addition to resting cell cultures maintained for 16 h in DEM without growth factor and hydrocortisone were 16,040; 12,030; 2,680; or 2,150 c.p.m. respectively. Therefore, the purified growth factor and hydrocortisone were not essential for the cyclic GMP enhancement of DNA synthesis but were included only to maintain a constant number of viable cells over a period of several days¹¹. In their absence, cellular viability as measured by the number of attached cells rapidly decreased after 48 h, and hence the results in Table 1 with the hormones present were obtained with non-degenerating resting cell populations capable of complete growth activation after serum addition (Table 1). The kinetics of induction of DNA synthesis were identical for serum or monobutyryl cyclic GMP addition to resting cultures: increases in DNA synthesis started at 14 to 16 h after additions (not shown). Addition of monobutyryl cyclic GMP to quiescent cultures^{7,12} of Swiss 3T3-4A, Balb/c 3T3 mouse cells, or baby hamster kidney cells seeded in 1%, 2%, or 1% calf serum respectively also caused a two- to three-fold stimulation of ^3H -thymidine incorporation into DNA over control cultures.

As the addition of cyclic GMP caused a significant induction of DNA synthesis presumably a certain fraction of the cellular population was induced to leave the resting state and enter the growing state. We then measured the intracellular concentration of cyclic GMP using a radioimmune assay¹⁰ at different times after addition of fresh medium and

serum to resting cultures of Balb/c 3T3 cells. Figure 1 shows that in addition to the two- to three-fold fall^{3,4,8} in the concentration of cyclic AMP shortly after medium change the concentration of cyclic GMP rose by a factor of eight- to eleven-fold over the value in unstimulated cultures reaching a maximum after 10 min. Thereafter the cyclic GMP value gradually declined and remained constant (within a factor of 2), although the cyclic AMP concentration rose again after 1 to 3 h to reach its maximum value before DNA synthesis (Fig. 1). Similar results were obtained with the 3T3-4A mouse line of cells (not shown). We also confirmed the changes in the relative cyclic nucleotide concentrations by radioactively labelling cells with ^{32}P - H_2PO_4 and directly isolating the cyclic nucleotides by chromatographic procedures. Table 2 shows that 19 min after fresh medium and serum were added to resting cultures of Balb/c 3T3 cells the cyclic GMP concentration was increased nine-fold, while the cyclic AMP concentration dropped by a factor of 2½-fold.

Fast, transient increases in the intracellular concentrations of cyclic GMP have recently been reported in other culture systems after administration of a mitogenic or mitogenic-like signal to quiescent cell cultures (for example, phytohaemagglutinin and concanavalin A on human peripheral blood lymphocytes¹³; insulin on rat fat cells or liver slices¹⁴), whereas cyclic GMP itself has mitogenic action on rat thymic lymphoblasts¹⁵ and can reverse the dibutyryl cyclic AMP inactivation of the immune response in precursors of antibody-forming spleen cells¹⁶. Here we have shown in the same culture system both the capability of relatively high (non-physiological) concentrations (10^{-6} to 10^{-4} M) of cyclic GMP to stimulate DNA synthesis in a significant fraction of quiescent mouse fibroblasts and large transient increases (ten-fold) in the concentration of intracellular cyclic GMP within a few minutes of exposure to a mitogenic signal (fresh medium and serum). Other events associated with transition from a resting to a growing state (increased protein and RNA synthesis¹²) are also stimulated by monobutyryl cyclic GMP addition to quiescent cultures (unpublished results). Exogenous addition of cyclic GMP may exert its mitogenic action by direct interference with the putative cellular growth-controlling machinery or by other less direct mechanisms such as the activation of the intracellular cyclic AMP phosphodiesterase¹⁷ to reduce cyclic AMP concentrations in the cell. The findings reported here, however, pose the possibility that cyclic GMP may act as a positive signal¹³ while cyclic AMP acts as a negative signal^{3,4,8} in the cell for controlling the growth of cultured fibroblasts.

We thank Dr R. Dulbecco for encouragement and support, Miss Margaret Seeley for technical assistance, and Miss Susan Schultz for help with the autoradiography. This work was supported by fellowships from the Helen Hay Whitney Foundation to P. S. R., the Deutsche Forschungsgemeinschaft to W. E. S., and a grant from the National Cancer Institute to Dr R. Dulbecco. We thank Dr D. Gospodarowicz for a gift of purified pituitary growth factor.

Possibility of inborn defect in isovalericacidaemia involving altered enzyme specificity rather than total inactivity

TANAKA, Isselbacher and colleagues¹ have described an inherited metabolic defect, isovalericacidaemia, which, though not fatal in their patients, leads, if untreated, to mental retardation and episodes of convulsion. As the name implies, the condition is characterised by high levels of isovaleric acid in the plasma. During periods of remission, this compound, which arises from the breakdown of dietary leucine, is excreted as a glycine conjugate. From the fact that only isovaleric acid accumulates and not butyric acid (from fat oxidation) or isobutyric or α -methyl butyric acids (from valine and isoleucine breakdown) Tanaka *et al.*¹ have concluded that there must be a specific isovaleryl CoA dehydrogenase that is non-functional in isovalericacidaemia. It had been assumed previously² that straight and branched-chain fatty acyl CoA compounds alike were oxidised by the green (that is, short-chain) acyl CoA dehydrogenase (see Fig. 1).

Sidbury, Smith and Harlan³ described an inherited neonatal condition in two unrelated families, the "odour-of-sweaty-feet" syndrome, in which the blood and urine apparently contained large amounts of hexanoate and butyrate. Symptoms of lethargy were followed by twitching, convulsions and death

within 2-3 weeks. Sidbury *et al.*³ attributed the condition to a faulty green acyl CoA dehydrogenase. Recent reanalysis of the origin samples by Ando *et al.*⁴ suggests that the original identification of the fatty acids was incorrect and that these also were cases of isovalericacidaemia. Ando *et al.*⁴ stress the need for rigorous identification of the characteristic compounds in establishing the existence of a new metabolic lesion.

Tanaka *et al.*^{5,6} noted several striking similarities between the symptoms of isovalericacidaemia and those of Jamaican vomiting sickness. The latter condition, frequently fatal, is not caused by an inborn error of metabolism but by the ingestion of a toxin, hypoglycin A, present in unripe 'ackee' fruits.^{7,8} Severe hypoglycaemia is accompanied in this condition by vomiting, and leads to coma. The hypoglycaemia has been attributed to abolition of a glucose-sparing effect in the under-nourished subjects through inhibition of fatty acid oxidation. Von Holt *et al.*⁹ suggested that methylenecyclopropane acetyl CoA, produced by the catabolism of hypoglycin A, might be an inhibitor of the short-chain acyl CoA dehydrogenase. Posner and Raben¹⁰ observed that hypoglycin also inhibits the oxidation of leucine, and Tanaka *et al.*⁵ have now shown that injection of hypoglycin A leads to greatly raised levels of isovaleric acid in the blood of rats. This they adduce in support of their contention that isovaleryl CoA dehydrogenase is a separate enzyme. They maintain that the coma in Jamaican vomiting sickness probably results from high levels of isovaleric acid rather than the low levels of glucose.

The view of isovalericacidaemia as an inherited deficiency of a specific and separate isovaleryl CoA dehydrogenase has already found its way into several respected textbooks. Bearing in mind, however, the strictures of Ando *et al.*⁴ with regard to chemical rigour, one should perhaps also proceed with caution in the biochemical interpretation of inborn errors of metabolism once the relevant compounds have been characterised. It is not impossible that a separate dehydrogenase exists for isovaleryl CoA, but so far no attempt has been made to purify it and demonstrate directly (1) that it is not the same as butyryl CoA dehydrogenase and (2) that one enzyme is absent or defective and the other present in isovalericacidaemia. The hypothesis also totally fails to explain the origin of the severe hypoglycaemia produced by hypoglycin A. It seems necessary, therefore, to re-examine critically the experimental evidence for the separate existence of isovaleryl CoA dehydrogenase.

In cases of isovalericacidaemia, during acute episodes the levels of isovaleric acid rise to about 30 mg per 100 ml, 500 times the normal figure. Levels of the other branched-chain fatty acids are not correspondingly elevated. In leukocytes from these patients the rate of oxidation of leucine to carbon dioxide is depressed ten-fold as compared with normal subjects. Rates of oxidation of other branched-chain amino acids were not measured.

Investigating the effect of hypoglycin A and its metabolites on rats, Tanaka *et al.*⁵ found that 0.7 mM α -ketomethylenecyclopropyl propionic acid (KMCP), a transamination product, inhibited conversion of 2-¹⁴C-leucine to ¹⁴CO₂ in liver slices by 87% and led to accumulation of isovaleric acid and its glycine conjugate. Their combined concentration was increased 180-fold. In addition, however, 2.1 mM KMCP inhibited isoleucine oxidation by 20% and led to accumulation of α -methylbutyrate (increased twenty-fold). Hypoglycin A itself (1.4 mM) also inhibited oxidation of isoleucine, though less strongly than that of leucine. Only valine oxidation was unaffected by hypoglycin A at this concentration. Leucine (60 mg per 100 g) orally administered to rats, following injection of hypoglycin A (10 mg per 100 g), raised the plasma level of isovaleric acid nearly 200-fold over the uninhibited control. In the same leucine-loading experiment, however, the level of butyrate was also raised forty-fold by the inhibitor. Moreover, in a similar experiment with

for the existence of a separate enzyme.

Dramatic early increase in uterine eosinophils after oestrogen administration

Two separate receptor systems for oestrogens, thought to be involved in independent mechanisms of oestrogen action, have been found to exist *in vitro* and *in vivo* in the rat uterus. These are the cytosol-nuclear receptor system and the eosinophil receptor system¹⁻³.

The cytosol-nuclear receptor system exists in the epithelial, stromal and muscular cells of the uterus². This receptor system is thought to be responsible, through a two-step mechanism⁴⁻⁶, for the genomic response, which involves an increased transcription of mRNA. The mRNA then codes for the synthesis of specific proteins and enzymes, a process which results in the true growth of the uterus. The genomic response is blocked by actinomycin D⁷⁻¹⁰, but is not counteracted by 11-oxygenated corticosteroids¹¹⁻¹⁴. Oestradiol-17 β has a much stronger affinity than oestriol for the cytosol-nuclear receptor system and accordingly oestradiol-17 β is the stronger oestrogen for the genomic response¹.

The eosinophil receptor system has been demonstrated *in vitro*^{1,15} and *in vivo*² in the uterine eosinophil leukocytes of the mature rat. The eosinophil receptors have a high affinity, a limited binding capacity and a great specificity for oestrogens, but not for compounds without oestrogenic activity^{1,16,17}. The uterine eosinophil receptor system is con-

sidered to be involved in some of the early oestrogenic responses in the uterus, such as water imbibition, increase in vascular permeability, histamine-releasing and oestrogen-priming effects^{1,18}. These effects are not blocked by actinomycin D¹⁹, but are diminished by conditions that produce uterine eosinopenia (such as 11-oxygenated corticosteroids and progesterone) and are enhanced under conditions that produce uterine eosinophilia (see ref. 18 for a review). Oestradiol-17 β and oestriol have similar affinities for the eosinophil receptors and accordingly, both hormones are strong oestrogens for the early oestrogenic responses¹.

The eosinophil leukocytes are not present in the uteri of immature or ovariectomised animals, and they are attracted to this organ under oestrogenic conditions^{16,20-24}. To understand the role and importance of the uterine eosinophils and the mechanism of eosinotaxis it is necessary to know the kinetics of the oestrogen-induced uterine eosinophilia at early times. Eosinophils have been reported to increase in the uterus 12 h after the parenteral administration of oestradiol benzoate to castrated mice or rats²⁵. The increase in uterine eosinophils at earlier times was, however, overlooked. Here we describe a dramatic increase in uterine eosinophils as early as 5 min after an intravenous injection of oestradiol to immature rats.

Female immature Wistar rats, weighing 50 g, were used in the present experiment. The solution of oestradiol-17 β in saline-ethanol was injected under ether anaesthesia in the jugular vein, using a dosage of 30 μ g per 100 g body weight. The control rats were similarly injected with equal amounts of saline-ethanol. The animals were killed at various times after the injection, and the uteri excised. The right uterine horn was used for biochemical studies and the left uterine horn was fixed in neutral formalin for subsequent histological studies.

The following parameters were measured for each animal: uterine wet weight, DNA²⁶, RNA²⁷ and protein²⁸ content, eosinophils per uterine section (counted on thirty to forty sections) and total number of uterine eosinophils. The latter was estimated by multiplying the average number of eosinophils per section by an appropriate factor, taking into account the thickness of the sections and the total length of the fixed uterine horn.

There is a dramatic increase in uterine eosinophils, clearly evident as early as 5 min after the intravenous injection of oestradiol to immature rats (Fig. 1). At this time, the total number of uterine eosinophils have changed from less than ninety in the controls to 1,150 in the treated animals. The count of eosinophils per section, as well as the total number of uterine eosinophils increases continuously until 12-24 h (Fig. 1), when the total number stabilises at about 150,000. After 24 h, the number of uterine eosinophils diminishes progressively.

The increase in the uterine wet weight first becomes evident 3 h after the oestrogen injection. Increases in the RNA and protein content first appear 6 h after oestradiol injection. None of the above responses are apparent 1 h after oestrogen injection (Fig. 1).

Examination of the histological material also shows that a large number of uterine eosinophils are found, at early times, attached to the wall of the uterine capillaries and small veins. The eosinophils first appear in the uterus in the mesometrial pole of the uterine horn, especially between the muscular layers and in the mesometrium itself. At later times, they are distributed homogeneously throughout the uterus, as previously described¹⁵.

The very early increase in uterine eosinophils after oestrogen administration is of striking importance in the elucidation of the role of eosinophils in the early oestrogenic response. The eosinophils began to appear in the uterus within minutes, that is, earlier than several other changes in the early parameters of oestrogen stimulation, such as the water

Fig. 1 Kinetics of oestrogen-induced uterine eosinophilia and other parameters of oestrogen stimulation. O, Total no. of uterine eosinophils; ●, average count of uterine eosinophils per section; Δ, uterine wet weight/DNA; ▲, RNA/DNA; ▽, proteins/DNA.

imbibition, histamine release and increase in RNA synthesis. An increase in cyclic AMP concentration is the only change reported at this very early time²⁹. Further data comparing the time sequences of early changes in cyclic AMP with the number of eosinophils in oestrogen-treated uteri are needed to discover if (and how) both parameters are related. The increase in cyclic AMP concentration has, however, been reported to be a transitory response²⁹, suggesting at least that the arrival of eosinophils in the uterus is independent of the continuous presence of cyclic AMP.

The rate of increase in the number of eosinophils in the present experiments suggests that the limiting factor of the oestrogen-induced uterine eosinophilia at early times, with the dose used in the present experiments, is the level of the eosinophils in the blood, which is low in the immature rat, and the production rate of eosinophils in the bone marrow.

The very early increase in uterine eosinophils after oestrogen administration suggests, although not conclusively, that eosinophils are directly attracted to the uterus by oestrogens. Previous *in vitro* and *in vivo* studies have demonstrated oestrogen binding by the uterine eosinophils^{1,2,15-17}. Autoradiographic studies of ³H-oestradiol *in vivo* have shown in eosinophils, besides the cytoplasmic localisation, the frequent appearance of silver grains along cytoplasmic interphases². This suggests the presence of a receptor for oestrogens near the cytoplasmic membrane of the eosinophils. *In vivo* studies have also demonstrated a higher concentration of labelled oestradiol along the walls of capillaries and small blood vessels in the rat uterus (unpublished data). The simultaneous presence of oestrogen receptors in the cytoplasmic membrane of the eosinophils and in the wall of the uterine capillaries and small blood vessels could be the key of the

organ-specificity of the oestrogen-induced uterine eosinophilia. It is possible that the oestrogens bound to the cytoplasmic membrane of the eosinophils also have affinity for receptors in the uterine capillary walls, thus allowing the attachment of the eosinophils to the capillary wall, which is the initial step towards penetration of the eosinophils into the uterus. The binding of oestrogens to the capillary wall may also induce conformational changes in its membrane which induces a specific attachment of the eosinophils to the capillaries. These hypotheses are under study.

2-Phenylethylamine as a possible mediator for Δ^9 -tetrahydrocannabinol-induced stimulation

If neuroamines modulate perception and affect, as implied in much of the literature, the behavioural effects of marihuana may be mediated by alterations of brain amine mechanisms. Even in large doses ($5\text{--}500\text{ mg kg}^{-1}$), Δ^9 -tetrahydrocannabinol (Δ^9 -THC) produces only relatively small changes in the brain levels and turnover of serotonin¹⁻³, catecholamines²⁻⁴ and acetylcholine⁵. We report here biochemical and behavioural experiments suggesting a role for endogenous 2-phenylethylamine (PEA) in the action of Δ^9 -THC. PEA may be one of the neuromodulators involved in wakefulness, arousal and excitement^{6,7}, and it is the precursor of phenylethanolamine, a putative neurotransmitter⁸. PEA is present in human⁸ and animal⁹ brain; monoamine oxidase B plays a major role in the metabolism of PEA whereas monoamine oxidase A is responsible for the deamination of noradrenaline and serotonin¹⁰. The observations that the urinary excretion of PEA is decreased in patients with endogenous depression¹¹⁻¹³ and that in animals brain levels of PEA are increased by antidepressive treatments [monoamine oxidase inhibitors (MAOIs), imipramine, electroshock^{7,9,14}] suggest that this amine is important in modulating affect.

Brain levels of 2-phenylethylamine were determined in rabbits (New Zealand, male, 2-3 kg) using the method of Mosnaim and Inwang¹⁵, which measures the ultraviolet absorbance at 287 nm of the reaction product of PEA with ceric sulphate and HCl. For behavioural observation, ten male white Swiss mice (25 g) were grouped in a plastic cage [$28 \times 18 \times 12$ (height) cm]. Two observers used a simple checklist to evaluate behaviour in a 'blind' fashion. The number of experiments is listed in Tables 1 and 2.

Table 1 shows that 1 h after acute intravenous administration of Δ^9 -THC (3 mg kg^{-1}), brain levels of PEA had increased approximately four-fold. None of the other drugs studied in mice⁹, rats¹⁴, or rabbits¹⁶ induced such a large increase in PEA brain levels. Intravenous administration of 0.3 mg kg^{-1} of Δ^9 -THC (once daily for 8 d) doubled PEA brain levels (note that the psychoactive dose of Δ^9 -THC in humans varies from 0.01 to 0.25 mg kg^{-1} (ref. 17)). This increase in PEA brain levels may be due to a decrease in the rate of PEA disposition: in rabbits, Δ^9 -THC increased the amount of labelled PEA recovered from brain tissue following the intraventricular administration of trace amounts of labelled L-phenylalanine or of labelled PEA¹⁸.

Rabbits treated with Δ^9 -THC (0.3 or 3 mg kg^{-1}) showed a transient phase of excitement, followed by catalepsy with hyperexcitability to auditory stimuli (startle response was evoked by a soft clapping which evoked only an alerting response in untreated rabbits). Pargyline (100 mg kg^{-1} , given intraperitoneally, 72, 48 and 24 h earlier) increased the initial excitatory effect of Δ^9 -THC.

In mice, Δ^9 -THC (5 mg kg^{-1}) reduced spontaneous motor activity, and induced hyperexcitability and episodes of postural arrest with staring. In contrast, when mice were pretreated with the MAOIs nialamide (Table 2) or pargyline (100 mg kg^{-1} , 48 and 2 h earlier; or 100 mg kg^{-1} , 72, 48 and 24 h earlier), Δ^9 -THC increased motor activity and induced hyperexcitability and episodes of stereotyped behaviour ('popcorn effect') during which all the mice in the cage jumped, ran and vocalised. These episodes (lasting seconds or minutes) were separated by periods of relative quiet and occurred either spontaneously or were evoked by auditory stimuli. In the doses used, nialamide and pargyline inhibit brain MAO, and pargyline increases the levels of endogenous brain PEA¹⁹. Thus, the ability of these MAOIs to unmask this behavioural stimulant effect of

TABLE 1 Increase in brain levels of PEA induced by acute or chronic intravenous administration of Δ^9 -THC dissolved in 1 ml of Tween 80.

Treatment	mg kg ⁻¹	Time between injection and death (h)	Brain PEA mg kg ⁻¹ wet tissue $\bar{X} \pm \text{s.e.}$	No. of groups
None	—	—	0.42 ± 0.17	6
Tween 80	—	1	0.58 ± 0.20	6
Δ^9 -THC	3	1	$2.30 \pm 0.76^*$	6
Tween 80	Once daily, 8 d	24	0.66 ± 0.23	6
Δ^9 -THC	0.3 Once daily, 8 d	24	$1.36 \pm 0.36^*$	6

Each group consisted of six male white New Zealand rabbits (2-3 kg).

* $P = 0.01$ (treatment compared with control).

Δ^9 -THC suggests that the latter is mediated by endogenous monoamines. Of the monoamines that may mediate the stimulatory effects of Δ^9 -THC, serotonin is an unlikely candidate because its behavioural effects are mainly depressant¹⁹⁻²¹; moreover, the serotonin depletor *p*-chlorophenylalanine (Table 2) enhances rather than prevents the stimulatory effect of Δ^9 -THC (after MAOI) (see also related observations in refs 22 and 23). Endogenous catecholamines seem to inhibit rather than to mediate the stimulating effect of Δ^9 -THC since the catecholamine depletor α -methyl-*p*-tyrosine unmasks or enhances the stereotyped and aggressive behaviour induced by Δ^9 -THC in mice (Table 2). Our results suggest that PEA mediates Δ^9 -THC-induced stimulation. PEA readily crosses the blood-brain barrier and its amphetamine-like behavioural effects are potentiated by MAOIs^{7,9}. As in the case of Δ^9 -THC, the administration of

	Δ^9 -THC	++	+	—

Δ^9 -THC was given in a dose of 5 mg kg^{-1} and was followed 1 h later by 6 mg kg^{-1} PEA. Mice were in groups of ten and each experiment was performed at least twice. All drugs were injected intraperitoneally (0.01 ml g^{-1} of body weight) and dissolved in saline; Δ^9 -THC was dissolved in saline and Tween 80 (24:1 (v/v)). Controls were injected with drug vehicles; saline controls were not different from untreated animals and are omitted from the table. Behaviour was evaluated by two observers in a blind fashion using a simple rating scale. The 'popcorn effect' is described in the text.

PEA (10 to 50 mg kg⁻¹) alone (without MAOI pretreatment) induced depression preceded by a brief stimulation, whereas in mice pretreated with MAOIs (doses as described above), PEA induced amphetamine-like stimulation, 'popcorn' behaviour and, less frequently, aggressiveness. PEA (6 mg kg⁻¹) did not significantly alter the behaviour of mice not pretreated with MAOIs and, in those that were pretreated it induced hyperactivity and a weak and brief 'popcorn' effect. Moreover, the stimulant effects of Δ^9 -THC and PEA are synergistic. In mice pretreated with nialamide (Table 2), the combination of Δ^9 -THC (5 mg kg⁻¹) and PEA (6 mg kg⁻¹, 1 h after Δ^9 -THC) induced marked hyperactivity, 'popcorn' behaviour and vicious fighting (defensive and aggressive postures, chasing, and biting to the point of drawing blood). A similar interaction between Δ^9 -THC and PEA was obtained in mice treated with pargyline except that fighting was not observed.

These behavioural experiments suggest that the observed increase in the brain levels of PEA induced by Δ^9 -THC are associated with an increase in free PEA available to receptor sites and that this is responsible for some of the stimulant effects of Δ^9 -THC.

These results were presented in part at the second international symposium on drug addiction in New Orleans, March 1973. We thank Mr Sam Myles for technical assistance. Drugs were supplied by the National Institute of Mental Health (Δ^9 -THC), Abbott Laboratories (pargyline), Pfizer Laboratories (nialamide) and Merck Sharp and Dohme (α -methyl dopa).

Regeneration of the ventricular myocardium in amphibians

REGENERATIVE capacity of the myocardium in vertebrates is reported to be minimal¹⁻⁶. Mauro has advanced the thesis that the absence of satellite cells in the cardiac muscle is responsible⁷. Most recently, Oberpriller and Oberpriller have reported mitosis in adult newt myocardial cells 16 d after minor trauma⁸. Here we report observations on the adult salamander which indicate that cardiac regeneration of great competency occurs in this animal.

The adult aquatic stage of *Triturus viridescens* was used, animals were stored in pond water in glass aquaria at room temperature and were fed chopped liver and beef twice weekly. Anaesthesia was obtained with 1:1,000 Tricaine (Ayerst) and the heart was approached through a midline ventral incision, splitting the sternum and incising the pericardial sac. Between 30% and 50% of the ventricular myocardium was removed with iridectomy scissors traversing across the ventricular cavity (Fig. 1) and the skin incision was closed with interrupted 4/0 silk sutures. The animals were immediately transferred to fresh pond water in finger bowls and after recovery, returned to glass aquaria. No antibiotics or other chemical agents were used. During recovery, skin capillaries were observed microscopically in the tail fin, using transmitted light. For histological examination, the heart was removed *in toto*, fixed in buffered formalin with subsequent routine processing in hematoxylin and eosin. For electron microscopy, the hearts were fixed in cold 4% phosphate buffered glutaraldehyde, post-fixed in osmium tetroxide and embedded in Epon. Thin sections showing silver-grey interference colours were stained with uranyl

FIG. 1 Longitudinal sections of triturus heart showing extent of ventricular resection. Resection partially completed, entering into ventricular lumen from the right, in direction of the arrow. Excess portions of the auricles have been trimmed away after fixation.

acetate and lead citrate and examined with an RCA EMU-2D electron microscope.

In an initial series of twenty animals, all survived the procedure for two weeks after which they were killed. Since then, several hundred animals have been used for various phases of the study with an overall mortality rate of 10%. Observation of the heart *in situ* by dissecting microscope immediately after ventricular resection revealed pronounced contracture of the myocardium at the resection site resulting in a decrease in the diameter of the opening into the ventricular lumen. Bleeding was noted to be initially brisk, decreasing rapidly and ceasing with clot formation at approximately 60 s.

Complete circulatory stasis occurred within 5 min of resection. Erythrocytes were always trapped in the observed capillaries and after a variable period of time (30–120 min), oscillatory movement of these cells could be seen, with no directional flow. Directional movement (in which pulsations as such were not visible) began generally at 90 to 120 min but once occurred as early as 1 h. Circulation was noticeably slower than normal and generally did not become normal until 3–5 h after resection. Twelve animals were followed using smears (Giemsa-Jenner stained) of the peripheral blood at 30 min intervals following resection. At 2 h after resection, immature erythrocytes first began to appear and reached a maximum 15%–20% at 5 h.

Specimens for histological examination were taken at 5, 15, 30 and 60 min and 2, 3, 5 and 24 h after resection. Normal, non-operated specimens were processed at intervals to check on technique; no mitotic figures were observed in either the control or any of the experimental specimens. In the early experimental specimens, the major part of the clot was frequently lost in the process of removal and fixation of the heart. Many immature erythrocytes were visible, however, in the retained portions of the clot which were closest to the injured myocardium. After 30 min, the clot appeared to have differentiated into two zones, one closest to the injured myocardium which was composed of small basophilic cells with darkly staining nuclei and a peripheral zone of normal appearing erythrocytes with eosinophilic cytoplasm. After 3 h, the area of the resection was filled with a tightly packed mass of the basophilic cells (Fig. 2) and the original peripheral erythrocytes were undergoing

Fig. 2 Longitudinal section through ventricular myocardium 3 h after resection (magnification scale as Fig. 1). The mass of basophilic cells is clearly distinct, from the remainder of the myocardium and appears to be approximately the same in extent as the original resected portion.

Fig. 3 Electron micrographs through site of ventricular resection two hours after resection; section through one of the cells bordering the defect, showing a region of active myofilament synthesis. Many polyribosomal complexes (C) are seen in close association with filamentous structures. z-band material and associated myofibrils (Z) are seen in the early stages of organisation. Mitochondria (M) show densely packed cristae and an electron-dense matrix and the sarcoplasmic matrix has a plaque embryonal appearance.

degeneration and nucleolysis. Between 3 and 5 h, the mass of basophilic cells diminished and slightly basophilic myocardial fibres appeared, which were arranged in a more open 'lattice-like' fashion than the remainder of the myocardium. By 24 h, sections appeared completely normal and there was no evidence of injury other than, occasionally, a small mass of degenerating erythrocytes exterior to the myocardium proper.

Specimens for electron microscopy were taken on the same time scale as for histological examination (except at 24 h). The early stages, 5 to 30 min, primarily showed the young forms of erythrocytes previously noted. The myocardium at the edge of the defect demonstrated several signs of degeneration in the 30 min specimen. By 2 h, the cells closest to the myocardial edge showed active fibrogenesis (Fig. 3).

Unquestionably, these animals can survive resection of up to 50% of the ventricular myocardium, with restoration of normal circulatory dynamics within 5 h. It seems that this is accomplished by some active cellular process with restoration of the missing myocardium rather than simple approximation of the cut edges and subsequent 'sealing off'. The origin of the reparative cells and the mechanism used to restore the myocardial mass is, as yet, unclear. If this represents a true regenerative process, it is more rapid and competent than any previously reported.

Thymine-labelled deoxyoligonucleotide involved in DNA chain growth in *Bacillus subtilis*

OKAZAKI *et al.* showed that bacteria labelled with short pulses of radioactive thymidine incorporate radioactivity into small DNA fragments, the so-called Okazaki pieces¹. These fragments have been observed in various bacterial, bacteriophage and eukaryotic systems^{2,3}. Pulse-chase experiments demonstrated that the Okazaki pieces are precursors of longer DNA chains, indistinguishable in length from the bulk of the DNA. Thus, the idea has arisen that DNA synthesis proceeds discontinuously on at least one of the two growing DNA chains of a given replication fork; that is, individual short DNA fragments are synthesised by a 5' → 3' DNA polymerase and then joined to the growing chain by ligase².

However, Werner has reported that cultures of *E. coli* labelled with short pulses of ³H-thymine incorporated radioactivity principally into large DNA; only a small fraction of the label was found in Okazaki pieces⁴. Furthermore, the fraction of the total label incorporated into Okazaki pieces increased rather than decreased with time of labelling during very short pulses. On the basis of these and other experiments, Werner concluded that DNA replication proceeds continuously without Okazaki pieces as intermediates⁴. Furthermore, he suggested that thymine and thymidine label separate precursor pools, thymine being used for replication and thymidine being incorporated primarily into Okazaki pieces involved in DNA repair⁵.

Using a thymine-requiring strain of *Bacillus subtilis*⁶, we decided to explore the possible differences between thymine (T) and thymidine (TdR) labelling of DNA. Cultures (80 ml) of *B. subtilis* *thy⁻ trp⁻* were grown in minimal medium at 25°C until late exponential phase (1.5×10^8 cells ml⁻¹), centrifuged and resuspended in 5 ml of fresh medium containing 5 µg ml⁻¹ T. The concentrated cells were incubated at 25°C for 10 min and then labelled with short pulses of ³H-T or ³H-TdR. Pulses were terminated with -20°C acetone, the cells lysed and the lysates sedimented in alkaline sucrose gradients.

Figure 1 compares the labelling patterns of cells pulsed with ³H-T against ³H-TdR. In both cases, most labelled DNA sediments slowly with an S value of 30 or less. Very little radioactivity is found at a position in the gradient corresponding to 75S, the sedimentation coefficient of bulk DNA under our conditions. (The radioactivity in the final fraction of each gradient is due to unlysed cells.) Figure 2 shows the labelling patterns found with longer pulses of ³H-T. Again, most labelled DNA sediments more slowly than bulk DNA. The S value increases gradually as the pulse time increases, in a manner similar to that reported by Okazaki *et al.* for ³H-TdR labelling of *B. subtilis*². The gradual transition shown in Fig. 2 is characteristic of *B. subtilis*; a significant number of intermediate size chains are observed, suggesting that joining of Okazaki pieces may be slower in *B. subtilis* than in *E. coli*².

Results similar to those seen in Figs 1 and 2 are also obtained by using unconcentrated cells, or by using a differ-

ent solution to stop the pulse (10% pyridine-20 mM KCN — 1 mM EDTA at 0°C)⁷. In all cases thymine labels

FIG. 1 Alkaline sucrose gradient sedimentation of pulse-labelled *B. subtilis* DNA. *B. subtilis* *thy⁻ trp⁻* was grown at 25°C in a medium containing 0.2% (NH₄)₂SO₄, 1.4% K₂HPO₄, 0.6% KH₂PO₄, 0.02% MgSO₄·7H₂O, 10⁻⁶ M FeSO₄·7H₂O, 10⁻⁷ M MnCl₂·4H₂O, 0.2% glucose, 0.2% Na₃ citrate·2H₂O, 0.2% casamino acids, 40 µg ml⁻¹ tryptophan, and 5 µg ml⁻¹ thymine. The doubling time is 110 min in this medium. For a single pulse labelling experiment, 80 ml of cells was grown to late exponential phase (1.5×10^8 cells ml⁻¹), collected by centrifugation at 4°C, and resuspended in 5 ml of fresh complete medium. The concentrated cells were shaken gently for 10 min at 25°C, then stirred vigorously with a magnetic stirrer, and pulse labelled with either 0.6 ml ³H-T (20 Ci mmol⁻¹, 1 mCi ml⁻¹) or 0.6 ml ³H-TdR (6 Ci mmol⁻¹, 0.1 mCi ml⁻¹). The pulse was terminated by the rapid addition of 20 ml of -20°C acetone. The cells were centrifuged at 4°C and then resuspended in 20 ml of a solution containing SSC (0.15 M NaCl, 0.015 M Na₃ citrate), 20mM KCN, 1mM EDTA. The cells were centrifuged again at 4°C and the cell pellet suspended in 0.15 ml of SSC containing 27% sucrose, 20 mM KCN, 10 mM EDTA, pH 8.2. A 25 µl sample of 40 mg ml⁻¹ lysozyme was added and the sample incubated for 30 min at 37°C. Then 0.05 ml of 10% sarkosyl and 0.1 ml of 1 M NaOH — 0.1 M EDTA were added. After gentle shaking, the cells began to lyse; 0.7 ml of 0.3 M NaOH and 30 mM EDTA were added slowly. The entire lysate was layered on top of a linear 5% to 20% (w/v) alkaline sucrose gradient containing 0.3 M NaOH, 0.5 M NaCl, 10 mM EDTA. Sedimentation was carried out in a Beckman L2-65B ultracentrifuge with an SW27 rotor spun at 20,500 r.p.m. for 16 h at 4°C. The centrifuge tubes were fractionated from the top with an Auto Densi-Flow fractionator (Buchler Instruments) into 19 fractions of equal volume. Individual fractions were precipitated by addition of 0.3 ml 0.1 M Na pyrophosphate, 0.3 ml 3 mg ml⁻¹ T, and 4 ml cold 15% TCA containing 0.50 mM Na pyrophosphate. The samples were kept at 0°C for 20 min, and the precipitates collected on nitrocellulose filters (Matheson-Higgins Co., 25 mm diameter, 0.45 µm pore size) which had previously been soaked in 50 mM Na pyrophosphate, 200 µg ml⁻¹ T. The filters were rinsed with cold 3% TCA, dried, suspended in a toluene-scintillator solution, and counted in a liquid scintillation counter. The S scale was determined using a Φ29 DNA marker (S = 26). a, cells pulsed with ³H-T; b, cells pulsed with ³H-TdR. Pulse time: ●, 8s; ○, 15s; ▲, 30s.

Fig. 2 Alkaline sucrose gradient sedimentation of pulse-labelled *B. subtilis* DNA ($^3\text{H-T}$). Conditions were as described in Fig. 1, except that $0.4 \text{ ml } ^3\text{H-T}$ ($12.6 \text{ Ci mmol}^{-1}$, 0.5 mCi ml^{-1}) was used for each sample. Pulse time: \circ , 15s; \bullet , 1 min; \triangle , 3 min; \blacktriangle , 6 min.

Okazaki pieces just as thymidine does, and the fraction of radioactivity in short DNA chains decreases rather than increases with the time of labelling. Pulse-chase experiments show that the thymine-labelled Okazaki pieces are precursors of larger DNA (data not shown). Independently, Okazaki *et al.* have shown that short pulses of $^3\text{H-T}$ are incorporated primarily into short DNA chains in both coliphage T4-infected cells and *E. coli*^{8,9}. Thus, there is no reason to doubt the common view that Okazaki pieces are intermediates in DNA replication, and that they can be labelled with either T or TdR.

We did observe one difference between T and TdR labelling of *B. subtilis*. In the case of $^3\text{H-T}$ labelling only, a significant amount of radioactivity can be seen in the top fraction (No. 1) of the sucrose gradients depicted in Figs 1 and 2. To separate the labelled material at the top of the gradient from Okazaki pieces, $^3\text{H-T}$ labelled lysates were sedimented for a longer time at a higher centrifuge speed. Figure 3 shows that a 15 s pulse of $^3\text{H-T}$ labels not only Okazaki pieces (fractions 9-14) but also a trichloroacetic acid (TCA)-precipitable component of about 2S (fractions 1-2). The 2S component is

labelled in very short pulses, before radioactivity appears in Okazaki pieces (Fig. 3).

We performed several control experiments to test if the rapidly labelled 2S component was actually a thymine-containing compound produced by live cells. First, we added $^3\text{H-T}$ to a non-radioactive lysate, centrifuged it through a sucrose gradient, and showed that there was no TCA-precipitable radioactivity in the gradient. Second, we noted that $^3\text{H-T}$, purified on a Sephadex G-25 column to separate it from potential macromolecular impurities, also could label the 2S component. Finally, we took fractions containing the 2S component from a sucrose gradient and treated them with formic acid, to hydrolyse the bases from the nucleic acids. Analysis of the hydrolysate by cellulose thin-layer chromatography demonstrated that the ^3H -labelled material co-chromatographed with a thymine marker, indicating that the 2S component is labelled with $^3\text{H-T}$ and not with a ^3H -labelled impurity.

To characterise the 2S component further, appropriate fractions were pooled from sucrose gradients, dialysed, and

Fig. 3 Alkaline sucrose gradient sedimentation of pulse-labelled *B. subtilis* DNA. Conditions were as described in Fig. 1, except that $0.6 \text{ ml } ^3\text{H-T}$ ($12.5 \text{ Ci mmol}^{-1}$, 1 mCi ml^{-1}) was used for each sample, and sedimentation was carried out at 26,000 r.p.m. for 40 h. The 16S sedimentation marker, a gift of C. Mulder, was $^{32}\text{P-SV40}$ DNA converted to the linear form by the R_1 restriction enzyme¹⁵. The first six fractions collected from each gradient were half the usual volume, in order to improve the resolution. Therefore, the fraction indicated as No. 4 was actually the seventh collected. Fractions 4-20 were then collected in the usual manner. a, 3s; b, 8s; c, 15s.

subjected to treatment with various enzymes. In some cases Okazaki pieces were treated in a similar manner. Table 1 shows that the 2S component is degraded to TCA-soluble material by pancreatic DNase, snake venom phosphodiesterase, *E. coli* exonuclease I or hot TCA. However, it is resistant to RNase A, pronase or alkali digestion. This indicates that the 2S component is a deoxyoligonucleotide with a 3'-OH end. Furthermore, as Table 1 shows, the deoxyoligonucleotide is resistant to spleen phosphodiesterase, but becomes sensitive to spleen phosphodiesterase after digestion with bacterial alkaline phosphatase. Therefore, the 5' end of the deoxyoligonucleotide must be phosphorylated.

TABLE 1 Effect of various agents on 2S component

Agent	% degraded to TCA soluble	
	2S component	Okazaki pieces
Pancreatic DNase	83%	85%
RNase A	5%	—
0.3 N NaOH	5%	—
Pronase	15%	—
Hot TCA	90%	—
Exonuclease I	86%	—
Snake venom phosphodiesterase	80%	85%
Spleen phosphodiesterase	10%	6%
BAP	6%	9%
BAP + spleen phosphodiesterase	67%	50%

BAP, bacterial alkaline phosphatase.

The 2S component was obtained by pooling appropriate fractions from sucrose gradients similar to those shown in Fig. 3. Okazaki pieces were obtained from sucrose gradients similar to those shown in Fig. 1b. Samples were dialysed against either SSC (0.15 M NaCl, 15mM Na₃ citrate) or the solvents described below, and then treated as described below. Pancreatic DNase digestion, with 20 μ g ml⁻¹ enzyme, was performed at 37°C for 1 h in 10mM Tris, pH 7.6, 10mM MgCl₂. RNase A, heated at 80°C for 10 min at pH 5 in 0.15 M NaCl to inactivate contaminating DNases, was used at 50 μ g ml⁻¹, 37°C for 30 min. Pronase, self-digested for 1 h, was used at 1 mg ml⁻¹, 37°C, for 5 h. *E. coli* exonuclease I digestion was in a 1 ml reaction mixture containing 10mM MgCl₂, 1mM mercaptoethanol, 0.1 M glycine buffer, pH 9.4, and 35 U of enzyme, at 37°C for 1 h. Snake venom phosphodiesterase digestion was performed in 5mM MgCl₂, 10mM Tris, pH 8.0, with 160 μ g ml⁻¹ enzyme at 37°C for 1 h. Spleen phosphodiesterase digestion was in 0.3 M ammonium succinate, pH 6.5, with 2.5 U enzyme ml⁻¹ for 1 h at 37°C. BAP digestion was in 0.1 M Tris, pH 8.0, with 6 U BAP ml⁻¹ for 1 h at 37°C. When BAP and spleen phosphodiesterase were used together, the solvent was 0.3 M ammonium succinate, pH 6.5. The samples were incubated with BAP alone for 1 h, then spleen phosphodiesterase was added, and the incubation continued for an additional 1 h. Alkali treatment involved 0.3 M NaOH for 16 h at 37°C. Hot TCA treatment involved precipitating the sample in 5% cold TCA, and then heating it to 90°C for 30 min. In all cases, samples were precipitated with cold TCA, filtered, and assayed for radioactivity as described in the legend to Fig. 1.

In view of the importance of RNA priming for DNA synthesis^{10,11}, the deoxyoligonucleotide was tested for RNA attachment at its 5' end. It was subjected to strong alkali treatment (2 M NaOH for 16 h at 37°C), and then digested with spleen phosphodiesterase, with and without alkaline phosphatase. If the deoxyoligonucleotide had RNA on its 5' end, the alkali would have hydrolysed the RNA, leaving a deoxyoligonucleotide with a 5'-OH end. Then it would have become susceptible to spleen phosphodiesterase. Table 2, however, shows that the deoxyoligonucleotide remains resistant to spleen phosphodiesterase, even after alkali treatment, unless it is also treated with alkaline phosphatase. Therefore, the deoxyoligonucleotide does not have even a single ribonucleotide on its 5' end. If RNA was originally present on the 5' end, then the RNA must have been degraded by nucleases either before or during extraction of the deoxyoligonucleotide from the cell.

To estimate the size of the deoxyoligonucleotide, it was subjected to Sephadex gel filtration. Figure 4 shows that the deoxyoligonucleotide is eluted from a G-100 column at about

the same position as a tRNA marker. Based on these data,

TABLE 2 Effect of alkali on the 5' end of the deoxyoligonucleotide

Enzyme	% degraded to TCA-soluble	
	Control	Alkali predigestion*
Spleen phosphodiesterase	13%	23%
BAP + spleen phosphodiesterase	69%	63%

BAP, bacterial alkaline phosphatase.

*Alkali predigestion: 2 N NaOH at 37°C for 16 h. For other experimental details, see Table 1.

as well as on the fact that it is TCA-insoluble, we conclude that the chain length of the deoxyoligonucleotide is in the range of 50-100 nucleotides.

Figure 3 shows that the deoxyoligonucleotide is labelled to maximum radioactivity within 8 s. Since we know the specific activity of the ³H-T in the growth medium, and can assume steady state labelling, the number of deoxyoligonucleotides per cell can therefore be computed. We calculate that there are ten to twenty deoxyoligonucleotides per cell.

Is the deoxyoligonucleotide involved in DNA replication? The following evidence suggests that it is. First, two specific inhibitors of DNA replication, 6-(*p*-hydroxyphenylazo)-uracil (HPUra) and nalidixic acid, inhibit synthesis of the oligonucleotide. The experiment with HPUra is particularly significant because its mode of action is understood; the reduced form of the drug inhibits *B. subtilis* DNA polymerase III, an enzyme required for DNA replication^{12,13}.

FIG. 4. Sephadex G-100 gel filtration of the deoxyoligonucleotide. Fractions containing the ³H-deoxyoligonucleotide were pooled from sucrose gradients similar to those shown in Fig. 3. They were neutralised and sedimented in CsCl to purify partially the deoxyoligonucleotide. Conditions of centrifugation in a Beckman L2-65B ultracentrifuge were as follows. The initial density of the CsCl was 1.7 g cm⁻³, SW65 rotor, 35,000 r.p.m. for 48 h at 10° C. The top 0.5 ml from each centrifuge tube was discarded and the remainder concentrated by dialysis against 30% polyethylene glycol. Finally, the deoxyoligonucleotide solution was dialysed against 0.1 M NaCl, 1mM Tris, 1mM EDTA, pH 7.0, and 0.2 ml applied to a Sephadex G-100 column equilibrated with the same solvent as above. The column size was 0.8 cm x 35 cm. Elution of the column with the solvent described above was at 25° C at 1 ml per 10 min. The void volume was determined using calf thymus DNA. The positions of wheat germ tRNA and thymine were determined by ultraviolet absorbance at 260 nm, and the position of the deoxyoligonucleotide by counting radioactivity as described in Fig. 1.

Pulse-chase experiments show that the deoxyoligonucleotide can be chased into larger DNA, although it is chased much more slowly (about 5 min) than it is labelled (Fig. 3). Because of the large deoxyribonucleotide pools in *B. subtilis* it is difficult to be sure that the oligonucleotide is chased directly into larger DNA. It could be broken down and the nucleotides re-used during the chase. There is an argument against breakdown and re-use; if cells are labelled with a short pulse of $^3\text{H-T}$ (which labels the deoxyoligonucleotide) followed by 5 min of incubation with 400 μM HPUra; the deoxyoligonucleotide is still found at its usual position near the top of a sucrose gradient. It is neither degraded nor chased into larger DNA. This suggests that the deoxyoligonucleotide is chased directly into larger DNA and not simply degraded and re-used during pulse chase experiments.

Hybridisation experiments show that the deoxyoligonucleotide hybridises with high efficiency, and equally well, to each of the separated strands of *B. subtilis* DNA; 11.3% of the radioactive deoxyoligonucleotide hybridises to the H (heavy) strand and 11.8% to the L (light) strand. (The separated strands were a gift of R. Rudner¹⁴.)

We do not understand why the deoxyoligonucleotide accumulates only after $^3\text{H-T}$ pulses (steady state labelling⁴) and not after $^3\text{H-TdR}$ pulses (non-steady state labelling⁴) in *B. subtilis*. Also, it is not observed after $^3\text{H-T}$ pulse-labelling of *E. coli* (our unpublished data and ref. 9). However, Jacobson and Lark, using T4 polynucleotide kinase to label the ends and hence count the number of chains in exponentially growing *E. coli*, found a large number of small DNA chains comparable in size to the deoxyoligonucleotide we observe⁷.

In summary, the following facts suggest that the deoxyoligonucleotide is involved in DNA replication. (1) It is labelled rapidly during pulses with $^3\text{H-T}$; (2) it can be chased into larger DNA, and (3) two inhibitors of DNA replication inhibit its synthesis. On the other hand, this evidence is also consistent with the possibility that the deoxyoligonucleotide is involved in DNA repair processes away from the replication fork. Further work is needed to determine the exact role of the deoxyoligonucleotide in DNA metabolism.

We thank Mrs J. Baird for advice, Dr N. Cozzarelli for *E. coli* exonuclease I, Dr C. Mulder for SV40 DNA, Dr R. Rudner for the *B. subtilis* DNA separated strands and the American Cancer Society for support.

Protease inhibitors do not block transformed cells in the G₁ phase of the cell cycle

PROTEOLYTIC treatment releases normal fibroblasts from density-dependent inhibition of growth (DDI)^{1,2} and induces surface properties characteristic of transformed cells. Furthermore, increased³⁻⁵ and altered⁶ protease activities are found in transformed cells. Also, a number of commercially available protease inhibitors including N- α -tosyl-L-lysyl-chloromethane (TLCK) selectively inhibit the growth of transformed cells⁷. All this has led to the suggestion that a protease-like activity is required by transformed cells for unrestrained growth⁷ and, by inference, that inhibition of this activity should restore 'normal' growth control (that is, DDI). In fact, TLCK lowers the saturation density⁷, de-

FIG. 1 DNA content of individual cells. a: 3T3 cells; shaded columns, log phase; open columns, at confluency. b-e: SV 3T3 cells; shaded columns, untreated controls; open columns, SV3T3 treated for 48 h with TLCK; b, 25 $\mu\text{g ml}^{-1}$; c, 50 $\mu\text{g ml}^{-1}$; d, 75 $\mu\text{g ml}^{-1}$; e, 100 $\mu\text{g ml}^{-1}$. All measurements calibrated with golden hamster lymphnode lymphocytes as reference (40 arbitrary units per cell).

TABLE 1 Effect of TLCK on proliferation and thymidine incorporation

Cell line	TLCK ($\mu\text{g m}^{-2}$)	Proliferation (doublings/24 h)		Mitosis per 10^3 cells	Thymidine incorporation	
		attached cells	total cells		c.p.m./ 10^3 cells (1 h pulse)	% labelled cells (4 h labelled)
SV 3T3	0	1.18 ± 0.20	1.19 ± 0.18	18.4 ± 3.8	125 ± 24	42 ± 4

	60	0.08 ± 0.07	0.17 ± 0.12	1.5 ± 1.4	56 ± 21	40 ± 2
	90	-0.21 ± 0.1	0.03 ± 0.03	0.1 ± 0.2	30 ± 20	42 ± 3
3T3 log phase	—	0.89	ND	12.6	105	32 ± 5
stationary phase	—	0.01	ND	0	1	2 ± 2

SV 3T3 cells were seeded in 3.5 cm Petri-dishes and allowed to grow to a density of approximately $10,000 \text{ cells cm}^{-2}$ (subconfluent). The medium was replaced and $20 \mu\text{l}$ of freshly made solutions of TLCK were added to each plate to give the final concentrations indicated. Thymidine incorporation was determined 24 h after the addition of TLCK, the mitotic and the labelling indices were determined 24 and 48 h after addition of TLCK. The number of cell doublings per 24 h was extrapolated from growth curves (5 points within 48 h). In addition to cells attached to the culture vessel, cells floating in the medium were also counted to give the total number of cells per plate. For comparison, untreated 3T3 cells in the log phase (about $20,000 \text{ cells cm}^{-2}$) and after reaching stationary phase were included in this experiment (five experiments with SV3T3; two experiments with 3T3). Figures in parentheses are % of the controls. ND, Not done.

creases the agglutinability with lectins and induces 'flat' morphology in transformed cells⁸. Here we present evidence that TLCK-inhibited cells are, however, not arrested in the G_1 phase of the cell cycle; thus, they do not meet a primary criterion⁹ for density-dependent inhibition of growth.

Freshly made solutions of TLCK (Calbiochem) were used for experiments. 3T3 mouse fibroblasts and their SV40 transformed derivative line (SV3T3) were used as the experimental cell lines. The procedures for the culture of the cells⁷, the growth inhibition studies⁷ and the thymidine incorporation⁸ have been published previously. Autoradiographs of cells grown on coverslips, labelled with ^3H -thymidine ($0.5 \mu\text{Ci ml}^{-1}$ medium; 5 Ci mmol^{-1}) for 4 h, were prepared with Kodak Bulk Emulsion NTB 2 and developed after 7 d exposure. To determine the mitotic index, cells were swollen and Orcein-stained according to the method of Fogh¹⁰. The DNA content of individual Feulgen stained cells was determined with an integrating microdensitometer (Barr and Stroud, Glasgow, Scotland). Two hundred to five hundred cells were measured per specimen at 560 nm, and the results expressed in arbitrary units. Lymph node lymphocytes from golden hamsters were placed on each of the microscope slides as reference cells.

The proliferation of SV3T3 cells is inhibited in a dose-dependent fashion by TLCK⁷; the inhibitory effect is mainly on cell proliferation and not simply due to detachment of cells from the plate (compare 'attached' and 'total' cells in Table 1), although there were some cells floating off into the medium, especially at high concentrations of TLCK. That TLCK inhibits proliferation is further supported by the fact that the reduced growth rate was paralleled by a decrease in the mitotic index (Table 1). The inhibition of cell proliferation was not, however, paralleled by a comparable decrease in DNA synthesis: even in TLCK-treated cultures where little or no net increase in cell number occurred, there was still considerable thymidine incorporation. Furthermore, the labelling index (4 h thymidine pulse) was not reduced by TLCK, although at higher concentrations of TLCK there appeared to be fewer grains (decreased by about 50%) over most of the labelled nuclei. By comparison, thymidine incorporation into 3T3 cells was drastically reduced after they became stationary (Table 1, bottom). Therefore, we conclude that TLCK does not stop transformed cells from entering the S phase.

This conclusion is further supported by measurements of the DNA content of individual cells in TLCK-treated cultures. In Fig. 1a, 3T3 cells are shown for comparison: there was a shift from the G_2 to the G_1 phase in 3T3 cells when they reached confluency. In contrast, in SV3T3 cells treated with increasing doses of TLCK (Fig. 1b-e), a shift to the G_1

phase did not occur. Rather, a dose-dependent shift to higher DNA content in the treated cells was seen. This seems to agree with the data in Table 1: the mitotic activity is reduced, but most cells continued to synthesise DNA (labelling index), although at a reduced rate.

In contrast to previous suggestions⁷, these results indicate that TLCK fails to induce density-dependent inhibition of growth in the sense that SV3T3 cells in the presence of this inhibitor are not arrested in the G_1 phase of the cell cycle.

We thank R. Bürk and Margaret M. Yarnell for helpful suggestions. We thank Dr H. Green of the Massachusetts Institute of Technology for the 3T3 and SV3T3 cells. A preliminary account of part of this work has been given at a recent meeting⁸. One of us (G. H.) is supported by the Swiss National Science Foundation.

The amino acid sequence of guinea pig C-peptide

THE discovery that the C-peptide of ox proinsulin is present in substantial amounts in the pancreas¹ has led the way to the study of C-peptides from a variety of mammalian species. The isolation and elucidation of primary structure has been described for the C-peptides of pig^{2,3}, man⁴⁻⁶, ox^{1,2,7,8}, dog, sheep and monkey⁹, rat¹⁰⁻¹², horse¹⁰ and duck¹³.

FIG. 1 Assignment of the primary structure of guinea pig C-peptide.

The horizontal arrows indicate the peptides liberated by the action of chymotrypsin (Chy) or cyanogen bromide (C) on the intact C-peptide and by the action of papain on the resulting fragments. The half arrows indicate amino acids released by stepwise degradation with carboxypeptidase A.

FIG. 2 Comparison of the amino acid sequence of the C-peptides of guinea pig and rat.

The primary structure of guinea pig C-peptide is that presented in this communication; the rat sequences have been reported^{10,12}. The horizontal line indicates residue common to the three structures. The differences between the three sequences appear to involve single base changes except at residues 8, 10 and 14 in the guinea pig. Residue 14 in the guinea pig is methionine whereas glycine occupies this position in the C-peptides so far reported.

The rodents, guinea pig, chinchilla and coypu, are classified in the suborder Hystricomorpha, principally on the basis of some anatomical and physiological characteristics. A knowledge of the primary structure of their proinsulins could contribute a molecular parameter to this classification. The amino acid sequence of their insulins is already known; the guinea pig sequence¹⁴ differs in 17 positions from that of coypu¹⁵ and coypu differs in 20 positions from chinchilla (N. R. Lazarus, R. Neville, and D. G. S., unpublished data). Elucidation of the primary structure of the corresponding C-peptides may provide further insight into the phylogeny of these species. Here, we present the amino acid sequence of guinea pig C-peptide.

C-Peptide was isolated from 2 kg (wet weight) of pancreatic tissue obtained from 350 Hartley strain guinea pigs. The method employed was essentially the same as that described previously⁴. The procedure yielded 8 mg of C-peptide and the homogeneity was assessed by analytical electrophoresis², NH₂-terminal analysis¹⁶ and amino acid analysis¹⁷. The sequence of amino acids was determined by quantitative techniques involving the isolation of fragments liberated by chymotrypsin, cyanogen bromide and papain (Fig. 1) and stepwise degradation of the individual peptides. Amides were assigned by comparison of the electrophoretic mobilities of peptides⁵ and by isolation of pyrrolidone peptides derived from NH₂-terminal glutaminyl peptides.

The results allow a comparison to be made between guinea pig C-peptide and the only available rodent C-peptides, rat I and rat II (Fig. 2). The guinea pig sequence differs in 13 positions from rat I and 12 positions from rat II. Within the order Rodentia, the suborders Hystricomorpha and Rattus can be distinguished not only by their insulins but also by their C-peptides. It remains to be seen whether the structures of the hystricomorph C-peptides, when these are available, will support the existing hystricomorph classification.

Second naturally occurring β -galactosidase in *E. coli*

SEVERAL studies have shown that the intestinal mucosa of various mammals contains at least two β -galactosidases¹⁻⁵. One of these has a primary specificity for lactose; the other has a primary specificity for synthetic β -galactosides such as o-Nitrophenyl β -D-galactopyranoside (ONPG). Since strains of *Escherichia coli* K12 bearing deletions of the *lac Z* gene have a very small residual activity toward ONPG, there must also be a second β -galactosidase in *E. coli*. We report here that *E. coli* K12 does indeed possess a second β -galactosidase. Although this enzyme has virtually no activity toward lactose, its synthesis is induced by lactose.

Strain DS4680A is a *lac* i^+ z^{del} y^+ strain. It is accordingly unable to ferment lactose and will not grow on lactose as a sole carbon source. Table 1 shows the amount of β -galactosidase activity in crude extracts of DS4680A grown in proline + IPTG (a gratuitous inducer of the *lac* operon) and grown in proline + IPTG + lactose. (IPTG is isopropyl 1-thio- β -D-galactopyranoside.) The β -galactosidase activity is induced to increase 230-fold by lactose. Since DS4680A had undergone no selection for β -galactosidase activity, this observation suggested that the activity occurs generally in *E. coli* K12 strains. We accordingly tested two additional *lac* Z deletion strains for the presence and inducibility of this activity. The tested strains (see Table 1) are unrelated to either DS4680A or to each other. In each there is a β -galactosidase activity induced by lactose (but not by IPTG), supporting the hypothesis that the gene for a second β -galactosidase does occur normally in *E. coli*.

TABLE 1 Specific activity of β -galactosidase in crude extracts of *lac* Z deletion strains

Strain	Uninduced	Induced	No. of experiments
DS4680A	0.131	30.2	3
W4680	0.112	20.9	1
2320M15	0.023	13.0	1
1011	<0.0015	<0.0015	1

Cultures were grown in phosphate minimal medium containing 0.1% proline as a carbon source, vitamin B₁, 2×10^{-4} M IPTG (uninduced) or with the addition of 0.2% lactose (induced). The cells were collected and ground with alumina and the nucleic acids precipitated with streptomycin sulphate. β -galactosidase activity was assayed at 37°C in 5 mM ONPG in 0.125 M KPO₄ buffer, pH 7.5, containing 5 mM Mg²⁺. One unit of activity is defined as the hydrolysis of 1 nmol of ONPG per min. Protein concentrations were determined by the method of Lowry *et al.*⁸ Tabulated values are in U mg⁻¹ protein. All strains are *E. coli* K12. All bear deletions within the *lac* Z gene and have functional *lac* permeases (*lac* Y^+). For purposes of comparison with the above values we have measured the specific activities of extracts of the wild type progenitor of DS4680A under these same conditions. The specific activity of an uninduced culture was 8.02 U mg⁻¹ protein; the specific activity of a culture in which the Z gene product was induced with IPTG was 11,865 U mg⁻¹ protein.

β -galactosidase II must have virtually no lactase activity *in vivo* since cultures in which the enzyme has been fully induced are not capable of growth when resuspended in lactose + IPTG minimal medium. The cells do have ample activity as measured by the hydrolysis of ONPG (10–30 U mg⁻¹) because strains can be selected that grow on lactose with as little as 16 U mg⁻¹. The enzyme is not cryptic *in vivo* because whole cells in which the β -galactosidase II activity has been induced are capable of hydrolysing ONPG. Therefore the failure of the cells to grow is probably due to an insufficient lactase activity.

β -galactosidase II has a small detectable amount of lactase activity *in vitro*. An extract of DS4680A in which the β -galactosidase II activity had been induced was prepared as in the legend of Table 1. The extract was permitted to hydrolyse lactose at a concentration of 139 mM under conditions identical to those described in Table 1. The reaction was terminated by heating for 10 min at 90°C. The amount of free galactose was assayed by the Galactostat assay system (Worthington), which uses galactose oxidase coupled with a chromogen. A unit of lactase activity is defined as the release of 1 nmol of galactose per min at 37°C. The specific activity of the extract toward ONPG was 41 U mg⁻¹ protein and toward lactose was 0.37 mg⁻¹ protein. This small amount of lactase activity detected *in vitro* is clearly not sufficient to permit the growth of cells in lactose.

By a procedure similar to that of Campbell *et al.*⁶ we have obtained derivatives of strain DS4680A that contain an evolved β -galactosidase (*ebg*⁺) which permits growth on

lactose as a sole carbon source⁷. A *lac*⁻ revertant of one of these strains was found to have lost both the ability to grow on lactose and the second β -galactosidase activity (see strain 1011 in Table 1), although it retains a functional *lac* permease. The simultaneous loss of both lactose fermentation and β -galactosidase II activity could possibly be the result of a double mutation. We have shown that *ebg*⁺ is closely linked to the marker *tolC* at 59 minutes on the *E. coli* map, there being 18.7% recombination between *tolC* and *ebg*. We crossed strain 1011 to the F⁻ *lac* Z^{del} Y^+ str^r *tolC* strain DLH-11 and selected str^r *tolC*⁺ recombinants. Sixty-eight such recombinants were scored for the presence of the inducible β -galactosidase II. Thirteen of the sixty-eight had such activity, giving a recombination frequency of 19.1% between *tolC* and the gene for the second β -galactosidase. Therefore the genetic position of the gene for the second β -galactosidase is the same as that of *ebg*⁺.

The function of the second β -galactosidase in both *E. coli* and in mammals is unknown¹, though there is the interesting possibility that their functions may be analogous.

Detection by DNA polymerase I of breaks produced in rat liver chromatin *in vivo* by alkylating agents

In previous papers it has been shown that the *in vitro* template activity of DNA¹ and chromatin² with DNA polymerase I of *Escherichia coli* is altered by the action of ionising radiation. These changes have been attributed¹ to the formation of new binding sites on the DNA for the enzyme, some sites being active in the synthesis of DNA and others inactive. These new sites are associated with single-strand breaks in the DNA. By working under conditions either of enzyme excess or of excess of template it is possible to distinguish between newly formed active and inactive enzyme binding sites.

These studies^{1,2}, along with the work of Kornberg *et al.*³ have shown that DNA polymerase I could be of value in the investigation of single-strand breaks in DNA under non-denaturing conditions (as opposed to the denaturing conditions used in the alkaline sucrose gradient centrifugation technique). Many agents lead ultimately to single-strand breaks in DNA. Here we wish to report the use of DNA polymerase I to investigate the *in vivo* formation of single-strand breaks in the DNA of rat liver chromatin following injection of two different types of methylating agent, namely dimethylnitro-

samine (DMN) and methyl methanesulphonate (MMS). DMN is a known hepatocarcinogen in rats, producing tumours when fed as part of the diet⁴, or when injected as a single dose to neonates⁵ or to partially hepatectomised animals⁶; MMS is not known to produce liver tumours⁷. A notable feature of the present study is that after injection of these agents single-strand breaks can be detected even after very short times and after very low doses.

Chromatin was prepared from rat liver at various times following injection of known amounts of the methylating agent. Chromatin prepared from untreated rats was used as a control. The rate of incorporation of ³H-dTTP into acid-insoluble material was used as a measure of the rate of DNA synthesis and this was taken as a measure of the template activity of the chromatin.

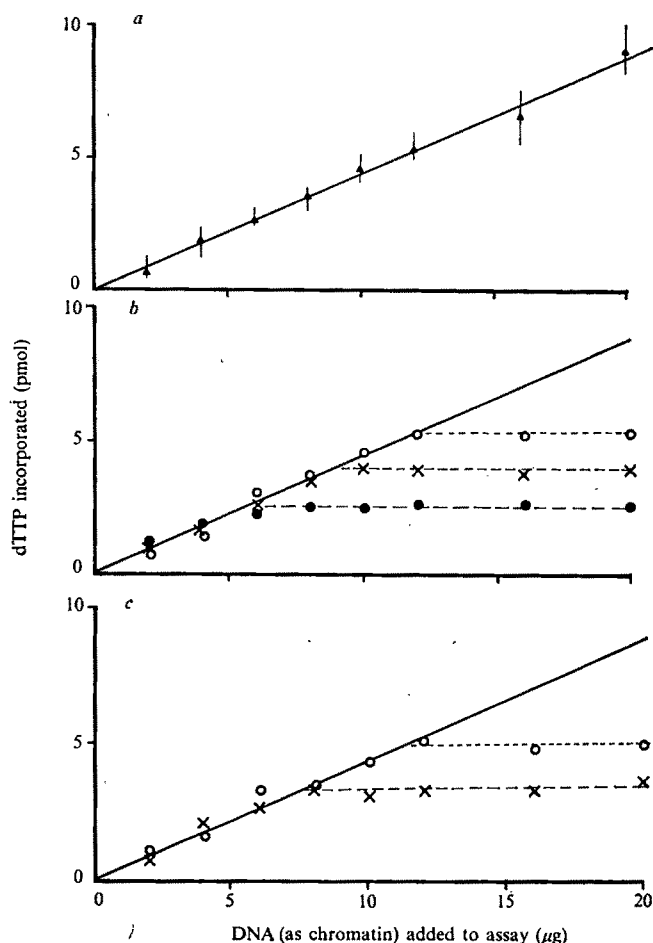

FIG. 1 Incorporation of dTTP into acid-insoluble material with increasing amounts of DNA (as chromatin) added to the assay. *a*, Control chromatin (▲); average of several independent experiments. The vertical lines indicate the range of values obtained. *b*, Chromatin following dimethylnitrosamine (DMN) treatment. The solid line shows control chromatin from *a*; ○, 2 mg kg⁻¹; ×, 14 mg kg⁻¹; ●, 30 mg kg⁻¹. *c*, Chromatin following methylmethanesulphonate (MMS) treatment. The solid line shows control chromatin from *a*; ○, 50 mg kg⁻¹; ×, 200 mg kg⁻¹. Rat liver chromatin was prepared from liver nuclei by the procedure described²⁰ for thymus chromatin: the nuclei were prepared by a modification of the method of Widnell and Tata²¹. Methylating agents were dissolved in normal saline and injected intraperitoneally. *E. coli* DNA polymerase I was prepared by a slight modification of Jovin *et al.*²²: the enzyme used was the phosphocellulose fraction that had been further purified by ultra-centrifugation in a glycerol gradient and contained no endonuclease I nor exonuclease III: 0.1 units were added to each assay. Details of the assay have been given elsewhere². Varying amounts of chromatin and water (to give a final volume of 0.3 ml) were added and thoroughly mixed before incubation at 37° C for 30 min.

The template activity of control chromatin increased linearly with the amount of DNA (as chromatin) added to the assay system up to at least 20 μg DNA per assay (see Fig. 1*a*). Under these conditions there is always an excess of enzyme over binding sites on the DNA present in the assay. Two factors preclude measurements of template activity at higher chromatin concentrations: (1) the difficulty of measuring small volumes of concentrated chromatin and (2) the large amount of precipitate since chromatin is insoluble in the assay mixture².

The template activity of chromatin from treated animals in all cases rises linearly with the amount of DNA (as chromatin) added to the assay mixture up to a certain level and is indistinguishable from controls; at higher DNA concentrations the template activity remains constant (see Fig. 1*b* and *c*). This maximum value depends, for any one sample of chromatin, upon the dose of methylating agent given, the time period between injecting the animals and preparing the chromatin, and the period of storage of the chromatin after preparation and before its assay. Figure 1 shows the dependence of incorporation of dTTP into acid-insoluble material, in 30 min, on the amount of chromatin added to the assay; in this experiment the chromatin was prepared 5 h after injection and was assayed as soon as possible (about 18 h after beginning preparation). Values are given for: (a) control chromatin, (b) chromatin prepared from DMN-treated animals, and (c) chromatin prepared from MMS-treated animals. Table 1 shows the variation of maximum template activity of the treated chromatin with dose and with period of storage of the chromatin at 4°.

Preliminary experiments (R. Saffhill, unpublished results) designed to measure the amount of DNA polymerase I that will bind to control and to treated chromatin using enzyme labelled with radioactive mercury⁸ (²⁰³Hg) have shown that chromatin from treated animals can bind at least 15 times more polymerase than control chromatin. Little, if any of this can be due to binding to chromatin protein. It has been shown that control chromatin does not bind DNA polymerase I inactively² since virtually all of the enzyme, apart from that bound actively to the chromatin is available, free in solution, for binding to poly (dAT)·poly(dAT). Further, irradiation of chromatin, which, like methylation, results in the formation of single-strand breaks, damaged bases, and apurinic sites does not produce an appreciable number of inactive enzyme binding sites². Finally, the ratio of the template activity (measured under conditions of template excess) of the DNA prepared from treated and control chromatin by centrifugation² in the presence of 2 M NaCl and *p*-aminosalicylic acid is similar to that obtained for chromatin itself, indicating that most or all of the inactive enzyme binding sites must lie in the DNA. Thus, *in vivo* treatment with methylating agents does in fact lead ultimately to the formation of single-strand breaks in the DNA that will bind DNA polymerase.

The single-strand breaks that are revealed in chromatin by DNA polymerase I are necessarily those in the regions of the DNA of the chromatin that are accessible to the enzyme. It has been shown² that only a small percentage of the DNA of chromatin is accessible to DNA polymerase and that this DNA lies within zones that are accessible to poly-L-lysine. Single-strand breaks are formed in other regions of the DNA but these would not be detectable in the present experiments. Thus, 'single-strand breaks' refer only to breaks in the regions of DNA in chromatin that are accessible to DNA polymerase I.

In vivo treatment with DMN and MMS leads (among other effects) to methylation of the chromatin: both the protein⁹ and the DNA¹⁰ are methylated. Very little is known about the methylation of the chromatin proteins apart from the fact that all of the histone fractions are methylated and the degree of methylation is considerably less than in the

DNA (H. K. Cooper, thesis submitted). The sites of methylation in the DNA are the phosphodiester backbone¹¹ (producing very stable phosphotriesters¹² which are believed to be associated with the so-called X₁-products¹³ and the DNA bases¹⁴. The major methylated bases detected are 7-methylguanine, 3-methyladenine and 6-O-methylguanine, the latter being found only after treatment *in vivo* with DMN and not after MMS treatment¹³. The maximum 7-methylguanine content of the DNA is found 5 h after DMN treatment and 2-4 h after MMS treatment: at these times similar levels of 7-methylguanine are produced after injection of 2 mg DMN per kg and 50 mg MMS per kg. The methylated bases are lost from the DNA both *in vivo* and *in vitro* and their half-lives have been measured and found to be 3 d, 2-3 h (G. P. Margison, and P. J. O'Connor, personal communication) and 13 h respectively for the *in vivo* loss of 7-methylguanine, 3-methyladenine and 6-O-methylguanine. There is some evidence for the involvement of enzymes *in vivo*¹⁵ although this is presumably accompanied by some chemical depurination to yield apurinic sites in the case of the unstable alkylpurines. The nature of the excision and repair process is uncertain. It almost certainly involves the formation of a single-strand break at or near to a methylated base (or an apurinic site formed on loss of a base) at some stage followed by repair, and rejoining of the DNA. Thus, in the experiments reported here we are observing the single-strand breaks produced as part of such a repair process.

With excess enzyme, the template activity will increase linearly with the amount of DNA added to the assay, that is, with the number of active binding sites added. At lower chromatin concentrations the treated chromatin is indistinguishable from controls, which indicates that among the new enzyme binding sites produced as a result of the methylation, there are no detectable active binding sites. Inactive binding sites however, would, under these conditions of excess enzyme, merely bind an enzyme molecule that would otherwise be free in solution and not synthesising DNA, that is, there would be no detectable effect on the template activity¹.

Once the DNA concentration of treated chromatin is sufficient to provide an excess of enzyme binding sites, there is no further increase in template activity with DNA concentration. Thus the lowering of the maximum template activity (the value of which is not measurable in practice with control chromatin) arises from the formation of inactive enzyme binding sites following the action of the methylating agent.

The number of single-strand breaks in a sample of chromatin relative to the number in control chromatin can be determined from its template activity. The single-strand breaks produced *in vivo* following methylation of the DNA must all be inactive binding sites as their effect can be detected only under conditions of enzyme saturation (excess of template)¹. Under these conditions of enzyme saturation the

TABLE 2 Presence of single-strand breaks in the DNA of rat liver chromatin following *IN VIVO* treatment with DMN and MMS

Time after treatment	Relative number of single strand breaks*		
	DMN 14 mg kg ⁻¹	DMN 2mg kg ⁻¹	MMS 50 mg kg ⁻¹
Control	1.0	1.0	1.0
15 min	8.8	<4	<4
1 hour	16.1	12.6	—
2 h	17.6	9.7	7.1
5 h	9.5	7.1	7.6
12 h	—	—	10.9
24 h	7.4	5.2	14.7
72 h	4.6	—	8.4
168 h	<4	—	4.5

* The number of single-strand breaks in control chromatin is taken as unity.

template activity of a sample of chromatin is proportional to the fraction of all binding sites that are active in DNA synthesis. Although the maximum template activity for control chromatin cannot be directly measured, it can be estimated² that enzyme saturation would occur at about 80 µg DNA per assay and that the maximum template activity would be about 35 pmol dTTP incorporated in 30 min. Until sufficient single-strand breaks have been formed in the DNA to saturate the enzyme by 20 µg DNA per assay (the highest level used in the present experiments), no difference between control and treated chromatin is detectable. At 20 µg DNA per assay the condition of enzyme saturation is reached when the number of single-strand breaks has increased about 3 times. Thus, chromatin with a template activity indistinguishable from controls up to 20 µg DNA per assay is referred to here as having less than 4 times the number of single-strand breaks present in control chromatin.

The presence of single-strand breaks was investigated at different times following injection of DMN and MMS. This is shown in Table 2. The time course for two different doses of DMN (2 mg kg⁻¹ and 14 mg kg⁻¹) is similar, the number of single-strand breaks present in the DNA increasing very rapidly within the first few minutes after injection of the DMN and reaching a maximum after 1-2 h. In the case of MMS at 20 mg kg⁻¹ there is no rapid increase in the number of single-strand breaks in the DNA; instead, the increase is gradual and the maximum number is not reached until about 24 h after injection. This difference is very much greater than the error of the experiments.

The higher the dose, the more single-strand breaks are present in the chromatin 5 h after injection (see Table 1) but the increase is not linear with dose. One possible reason for this is that the degree of methylation is far in excess of the excision capacity of the cell which, presumably would be

working at maximum capacity at all doses.

The decrease in template activity (corresponding to an increase in the number of single-strand breaks in the DNA) of treated chromatin on storing could reflect some *in vitro* chemical depurination (loss of methylated purines), and subsequent hydrolysis of the apurinic sites to give inactive binding sites, certain methylated bases being known to be lost quite quickly from DNA *in vitro*¹⁶. The single-strand breaks arising from hydrolysis of apurinic sites by the proposed β -elimination¹⁰ would be expected to be inactive binding sites since they would lack the 3'-hydroxyl group that is necessary for DNA synthesis to take place³. Alternatively, the decrease could arise from the action of a contaminating exonuclease which acts upon methylated or apurinic DNA to give inactive enzyme binding sites: the enzyme being absent or not detectable in control chromatin which shows no change in template activity on storing.

In the experiments reported here we are observing the presence of single-strand breaks, within limited regions of the DNA (accessible to DNA polymerase I), which may be formed at several stages of the repair process. Other workers have followed the methyl groups remaining unexcised in the DNA^{12,15} or the single-strand breaks shown by alkaline sucrose gradient centrifugation^{17,18}, a procedure which reveals also potential single-strand breaks in the DNA (for example, apurinic sites which yield single-strand breaks under alkaline conditions).

We have shown here that within the first few minutes of DMN treatment there is a large increase in the number of single-strand breaks present in the DNA, indicating a very rapid methylation followed by a rapid removal of some of the methylated bases. The observed *in vivo* loss of 7-methylguanine cannot account for this although it is possible that the observed rates of removal of 3-methyladenine and 6-O-methylguanine could do so. Other possibilities are that other, more labile methylated bases are produced and are responsible, although these have not yet been detected (no studies have been made of the methylated base content of the DNA at very short times after injection), or that there is a very rapid enzymatic excision of some of the methylated bases from certain regions of the DNA.

The reason for the difference in the time course of single-strand breakage after DMN and MMS treatment is uncertain. It could be that the two agents methylate different regions of the DNA since they are chemically different in their mode of action: some, or all, of the regions methylated by DMN being more rapidly excised than those methylated by MMS. Another possibility is that MMS methylates and inactivates some of the enzymes involved in the repair process with a consequent delay in repair.

In summary, we have shown that methylation of DNA *in vivo* affects the template activity of chromatin for DNA polymerase I by producing single-strand breaks. A relatively large effect is detected after low doses of methylating agent and (in the case of DMN) at very short times after injection. Functional changes have not previously been found after very low doses of these agents. The results demonstrate also the usefulness of DNA polymerase I in the investigation single-strand breaks in DNA. Since the single-strand breaks produced as a result of the methylation are all inactive enzyme binding sites (they bind DNA polymerase but DNA synthesis does not take place), the 3'-hydroxyl group at the break must be blocked, presumably by a phosphate. This is indicative of the type of endonuclease acting upon the methylated and apurinic DNA. Recently endonucleases that specifically attack apurinic sites in DNA have been discovered¹⁹ but nothing is known of their specificity.

To determine the possible relevance of these results to carcinogenesis we intend to study the effect of mixture of DMN and MMS upon the template activity of chromatin prepared from various tissues, along with the effect of other

carcinogens.

We wish to thank Mrs J. M. Margison for injecting the animals. The work was supported by grants from the Medical Research Council and the Cancer Research Campaign.

Detection and radioassay of soluble circulating immune complexes using guinea pig peritoneal exudate cells

METHODS at present available for the detection and quantitation of soluble circulating immune complexes include precipitation with Clq in agarose gel diffusion¹, precipitation with monoclonal rheumatoid factor², ultracentrifugation with inhibition of antibody-mediated lymphocyte cytotoxicity¹⁰, and precipitation with an optimal concentration of polyethylene glycol^{2,3}. These procedures either involve the use of substances isolated by fairly laborious means, or take some time to yield results. Preliminary tests in this laboratory showed that aggregated human immunoglobulin ingested by guinea pig macrophages was easily detectable by immunofluorescence, and that similar inclusions could be demonstrated after exposure of macrophages to systemic lupus erythematosus (SLE) sera.

We have used radioassay to measure uptake, and report here a new method applying the principle of competitive inhibition to the ability of guinea pig peritoneal exudate cells to ingest soluble immune complexes. The method takes only a few hours, and can detect as little as 25 ng of soluble immune complexes. Preliminary results showed the presence of complexes in twenty-two out of twenty-five randomly selected SLE sera (88%) and in none of twenty-five normal human sera. By the polyethylene glycol method, performed as described below, seventeen of the same twenty-five SLE sera

(68%) were positive for complexes as judged by the percentage of their total IgG precipitated.

Macrophages obtained about 5d after intraperitoneal injection of guinea pigs with sterile liquid paraffin were thoroughly washed in medium 199 three times by gently sucking up and down with a Pasteur pipette for 3 min and centrifuging at 500g for 7 min. The cells were then treated with human gamma globulin at a final concentration of 6%, and after another wash cellular debris was removed as described by Shortman *et al.*⁸. Human gamma globulin aggregated by heating at 63°C for 15 min was labelled with ¹²⁵I using the chloramine T method⁴ to produce labelled aggregate at a concentration of about 10 mg per ml.

Sera were tested for their inhibitory effect on uptake of labelled aggregate by the macrophages as follows. Tests were set up in triplicate in Falcon tubes containing 750,000 cells in 0.5 ml of medium 199 to which were added 10 μ l of a 1:5 dilution of serum in phosphate buffered saline (PBS), pH 7.4, and 10 μ l of the labelled aggregate solution diluted to give about 5000 c.p.s. The serum and aggregate were added simultaneously. In the control test, PBS was substituted for serum, in order to determine maximal uptake of labelled aggregate in the absence of competing serum. Cell counting was standardised by using a Coulter counter. All sera tested were decplemented by incubating at 56°C

Fig. 1 Inhibition by human sera of uptake of labelled aggregated human gamma globulin by guinea pig macrophages. Percentage inhibitions and means for twenty-five SLE sera and twenty-five normal sera are shown under -DNase. Also shown is the effect of pretreatment of the sera with DNase. DNase I was added to the sera to a concentration of 50 μ g ml⁻¹, and the mixtures incubated at 37°C for 1 h in the presence of Mg²⁺. The mean inhibitory activity of the SLE sera was significantly ($P < 0.001$) reduced. As well as normal sera, sera from forty-one patients with diseases other than SLE were tested: osteoarthritis (10), ankylosing spondylitis (5), scleroderma (5), sarcoidosis (5), acute appendicitis (4), peritonitis (2), chronic bronchitis (5), carcinoma of the bronchus (2), carcinoma of the stomach (1), and carcinoma of the prostate (2). All gave inhibition within the normal range.

Fig. 2 Dose/response curve for inhibition of uptake of labelled aggregate by HSA/anti-HSA complexes. HSA/anti-HSA soluble complexes were prepared by determining the equivalent proportions and adding 50 times antigen excess to the antiserum. The precipitate forming after incubation was discarded and the supernatant containing the soluble complexes used in the test. The figures shown in the ordinate represent the protein content of various dilutions of the supernatant.

for 30 min, and centrifuged at 1000g for 20 min. Fresh sera, as well as sera frozen at -20°C could be used. After the addition of serum and aggregate, the tubes were incubated at 37°C for 75 min during which they were gently shaken about once every 15 min to ensure continuous and thorough mixing of the cells with the sera and aggregate. It is important to avoid mixing by inversion or the use of a rotator as this leads to loss of cells by adherence to the caps of the tubes. The cells were then washed carefully three times by centrifugation only (avoiding sucking up and down for the same reason), using medium 199 and making sure that the cells after each wash were not disturbed during the pipetting off of the supernatant. It was found best to leave a small volume of the supernatant over the pellet, and to resuspend the cells in it by a gentle shake before adding fresh washing medium. The final pellet comprising macrophages and their ingested materials was suspended in medium 199 and its radioactive content determined by counting in a Gamma Guard 150 (ICN Tracerlab).

Iodinated monomeric human gamma globulin diluted to give the same number of c.p.s. as the aggregated human gamma globulin was added to triplicate tubes treated in the same way, and the mean count was subtracted as blank.

Figure 1 shows the inhibition of uptake of labelled aggregate in the presence of competing serum, expressed as a percentage of the maximal uptake in the absence of competition. It can be seen that SLE sera exert a more pronounced inhibitory effect than normal sera. That the inhibitory effect of SLE sera is probably due to the presence of soluble immune complexes was demonstrated by an experiment in which a solution of artificially prepared complexes of human serum albumin (HSA), and rabbit anti-human serum albumin (anti-HSA), in 20% normal human serum (NHS), was substituted for SLE serum. Figure 2 shows the dose/response curve obtained by adding labelled aggregate in competition with various amounts of HSA/anti-HSA complexes in this way. The antiserum from which the complexes were prepared was added in place of PBS in the control test.

It was found that as little as 25 ng of complex exerts significant inhibition—an indication of the sensitivity of the method. With this graph as calibration, the amount of soluble complexes present in test sera is readily determined after making corrections for the dilution factor.

Polyethylene glycol (PEG) at suitable concentration precipitates soluble immune complexes. Precipitates obtained from five of the positive SLE sera by adding 0.5 ml of a solution of PEG in borate buffer, pH 8.5, to equal volumes of 1:25 dilutions of the test sera in borate buffer to reach a final concentration of PEG of 7.5% were recovered by centrifugation and redissolved in PBS. The resulting solution was inhibitory in the test whereas the supernatant serum after the addition of PEG showed no inhibition. This is additional evidence that soluble immune complexes are responsible for the inhibition.

Fractions were obtained by gel filtration of serum samples on columns of Sephadex G150, and their inhibitory activities were measured and compared with their IgG, IgM and IgA content as determined by radial immunodiffusion assay⁶. Figure 3 shows results with one SLE serum fractionated in this way; the peak of inhibitory activity occurred in fractions of larger molecular size than IgG. The fact that no IgG was detectable by the Mancini method in the earlier of these inhibitory fractions may be accounted for by the greater sensitivity of the inhibition test. It was further shown in this experiment that when the inhibitory fractions were precipitated with PEG at a final concentration of 7.5%, the resulting supernatants had lost their inhibitory activity.

In an experiment using DNase, we have shown that part of the inhibitory effect produced by SLE sera may be due to the presence of DNA/anti-DNA complexes by demonstrating a reduction in inhibition following DNase treatment. Figure 1 shows that treatment of twenty-five SLE sera with DNase reduced their mean inhibitory activity by about 25%, in agreement with the results obtained by Creighton² with the PEG method.

When complexes of HSA with ¹²⁵I-labelled rabbit anti-HSA prepared at various antigen-antibody ratios were added in competition with SLE serum in the inhibition test described above, we found (Fig. 4, shaded portion) that the relative inhibitory effect of SLE serum increased with increasing antigen excess in the competing artificial complex. As well as providing further confirmatory evidence that the inhibitory effect of this serum is due to the presence of immune complexes, this observation suggests a simple ap-

FIG. 3 Chromatography on Sephadex G150 of serum from one SLE patient showing the position of the inhibitory complexes. ○—○, Absorbance of fractions at 280 nm; □—□, IgG content of fractions; ■, inhibitory fractions.

FIG. 4 The inhibitory effect of an SLE serum on the uptake of labelled HSA/anti-HSA by guinea pig macrophages. HSA/anti-HSA complexes were prepared by determining the equivalent proportions and adding 50 times, 25 times, 5 times, and 2 times antigen excess to a constant volume of antiserum. proach to the study of molar ratios in circulating soluble immune complexes.

Many factors may contribute to the inhibitory effect of sera on the phagocytosis of soluble labelled aggregate by guinea pig peritoneal exudate cells, including serum levels of IgG, serum complement levels, the presence of receptors for IgG and complement on the macrophage surface⁷, and the concentration of certain electrolytes, notably calcium⁸. For these reasons, the sera tested by this procedure were heat inactivated, and the cells were pretreated with human gamma globulin to 'block' surface receptors. The non-specific inhibitory effect of normal sera was thereby significantly reduced to a mean figure of 12.50% with 20% as the upper limit. The formation of soluble aggregates during heat inactivation may contribute to the inhibitory effect of sera, and very recently we have found that the use of heated sera in the test may be avoided by preliminary incubation of the cells with fresh guinea pig serum. This serves the dual purpose of 'blocking' both the complement receptors and at least some of the IgG receptors on the macrophages, and appears to obviate the need for pretreatment with foreign immunoglobulin.

The ability of foreign (guinea pig) macrophages to ingest soluble immune complexes present in human sera raises the question why human phagocytic cells do not *in vivo* by a similar process prevent such complexes persisting in the circulation, and eventually mediating tissue damage. One explanation might be that the level of circulating complexes in SLE can exceed the phagocytic capacity of blood monocytes and other phagocytes such as Kupffer cells. So far, however, we have been unable to obtain convincing evidence that human blood monocytes in SLE ingest soluble complexes *in vivo*. It is perhaps more likely that, although the

capacity of guinea pig macrophages to recognise the immunoglobulin moiety of complexes is inhibited by pretreatment with human immunoglobulin, the conditions of the test as carried out nevertheless increase the degree of denaturation of the antibody molecules in the complexes enough to enhance their ingestion.

We thank Mrs Ella Stephenson, Mr Paul Embling, and the staff of the Haematology Department, in particular Mrs C. Billing, for their assistance. We are grateful to Dr John Watkins, Dr Donald Rajapakse, and Dr Papamichail for their useful advice. One of us, I.I.O., is in receipt of a grant from the Commonwealth Medical Association for work leading to an MD thesis.

Evidence against recessive inheritance of susceptibility to the chronic carrier state for hepatitis B antigen

THE discovery of Australia antigen (Au), now designated hepatitis B antigen (HBAG), and its association with type B viral hepatitis stimulated application of a variety of serological assays for the detection of HBAG and anti-HBAG in pretransfusion screening of donors' blood and epidemiological work relating to transmission of hepatitis¹⁻⁶. The reasons for chronic prevalence of HBAG in apparently healthy carriers, who form an epidemiological reservoir of hepatitis B virus (HBV), remain ill-defined. Based on family studies with HBAG, Blumberg *et al* proposed a hypothesis that the persistence of HBAG for long periods is evidence of a genetic susceptibility which is inherited as a simple recessive trait^{7,8}. The extensive family data, however, included no pedigree with progeny of two parents positive for the antigen. Such a family is crucial to lend validity to the genetical hypothesis. An independent study in Italy supported the hypothesis with certain qualifications⁹.

In reviewing the mass of published family data, Petrakis made the most critical observation that only one family in Sardinia had two parents positive for HBAG and only two of their seven children were positive for HBAG; this did not support the genetic hypothesis⁹. It is tenable however that the postulated inherited susceptibility would be shown only when people are exposed to the infectious agent, and it is conceivable that the remaining five children in the Sardinian family had not been exposed to HBV. A pedigree with two HBAG carrier parents and their progeny of three children

FIG. 1 A Chinese family with HBAG chronic carrier parents and a child with specific antibodies to HBAG. The other two children had neither HBAG nor anti-HBAG. Ag = HBAG; Ab = anti-HBAG.

were investigated for HBAG and anti-HBAG and the results presented in this report, provide the first discrete evidence against the genetic hypothesis.

Tests for HBAG and anti-HBAG in the sera were performed by gel diffusion analyses, counterelectrophoresis and haemagglutination assays^{4,10}. Radioimmunoassay for HBAG in the sera negative by other methods was performed according to the instructions of the manufacturers of the kits (AUSRIA™, Abbott Laboratories, Chicago). The specificity of HBAG detected in any serum was confirmed by a line of identity with a known positive control serum in gel diffusion analysis. The specificity of the antibodies was confirmed by serological neutralisation of four units of antibodies with a known HBAG-positive serum and also by 10 µg of purified HBAG¹¹. Serum samples from both parents were tested in the clinical chemistry laboratory for liver function tests.

The results of HBAG and anti-HBAG testing of each member of the pedigree are shown in Fig. 1. HBAG was consistently detected in the serum of both parents in repeated testing of their specimens obtained on three occasions over a period of six months. Both parents were in excellent health, had no apparent physical problems, and clinical or biochemical results suggested absence of liver abnormality. It was concluded that they were asymptomatic chronic carriers of HBAG¹². Both parents are immigrants from the People's Republic of China. The three children were negative for HBAG in repeated testing of their sera by every method including radioimmunoassay. The 10-yr-old son, however, had specific anti-HBAG with a titre of 256 in haemagglutination assay. The 5-yr-old daughter and 3-yr-old son had no antibodies. The absence of HBAG, but the detection of specific high titre anti-HBAG in the eldest child was considered unequivocal evidence of past exposure to HBAG. The fact that the boy failed to become a chronic carrier of HBAG but produced an immune response in the form of antibody production provides crucial evidence against the susceptibility for the chronic carrier state inherited as a simple autosomal recessive trait.

Tests for anti-HBAG in families similar to the one reported here may provide additional evidence against the genetic hypothesis. With an average incidence of three healthy HBAG-positive persons per 2,000 adults in the United States of America, the possibility of detecting such matings at random is small. The family clustering of HBAG-positive individuals is more likely a function of an increased opportunity for environmental exposure to the infectious agent than the recessively inherited susceptibility^{9,13}. These considerations may prove valuable in genetic counselling occa-

sionally sought by chronic carriers, particularly amongst informed professionals who are medically and epidemiologically more concerned about the infectivity of chronic carrier state.

This work was supported by a research grant from the Center for Disease Control and by a contract with the Blood Resource Branch of the National Heart and Lung Institute of the United States Public Health Service.

Amino acid sequence change associated with genetic marker Inv(2) of human immunoglobulin

IMMUNOGLOBULINS are proteins composed of two heavy and two light chains covalently linked by interchain disulphide bonds¹. There are two types of light chains, κ and λ . The κ type human light chain is associated with an antigenic marker called Inv (ref. 2). Three types of antigens are recognised namely Inv (1), Inv(2) and Inv(3). Ropartz, Rivat and Rousseau³ have shown that these Inv markers are inherited through a series of three alleles *Inv*^{1,2}, *Inv*¹ and *Inv*³. About 98% of Caucasoid individuals who have the Inv(1) antigen also have the Inv(2) antigen³. Since fewer than 20% Caucasoids have the Inv(1, -2) phenotype⁴ it follows that the *Inv*¹ allele is rare in this race.

The Inv markers are associated with the presence of leucine and valine in position 191. Residue 191 is leucine in the case of Inv (1, 2) and valine in the case of Inv(3) in monoclonal κ chains^{5,6} and in normal polyclonal light chains⁷. The primary sequence associated with the third antigen, Inv (1, -2), has remained unknown.

We now report studies of a κ -Bence Jones protein, Cro, which is Inv(1, -2, -3). Figure 1 shows the Inv phenotype of the kindred of the patient. It seems reasonable to assume that an *Inv*¹ allele is present in this family and that the failure to detect Inv(2) in the Bence Jones protein is not an artefact caused by the patient's disease.

Protein Cro was purified, reduced, carboxymethylated and digested with trypsin. All the tryptic peptides of the C region

FIG. 1 Pedigree of the Cro family. X = Phenotype Inv (1, -2, 3). / = Phenotype (-1, -2, 3). Blank = not tested.

were isolated. They all had an amino acid composition identical to the corresponding homologous tryptic peptides of a κ chain except for peptide TIar. The latter peptide could be ascribed to position 150-169 by homology but did not contain alanine and it had an extra valine. The N-terminal sequence of peptide TIar was determined using the combined procedure of dansylation for N-terminal analyses and Edman degradation⁸. The result obtained was

Val-Asx-Asx-Val-Leu (Glx₅, Ser₄, Gly, Asx₂, Val, Thr) Lys

The fourth position is occupied by alanine in all the other known κ chains.

Peptide TIInBR (position 191-207) contained two leucines and two valines in its composition indicating that position 191 was leucine. In addition one of us (A.G.S.) isolated from the aminoethylated κ chain a tryptic peptide with an amino acid composition (Leu, Tyr, Ala)Cys which by homology with known chains can be situated in position 191-194.

The relation between Inv phenotype and primary structure of the C region of the κ chain is therefore as shown in Table 1. The last combination of residues has not been observed and may not exist since it seems likely that the allele Val₁₅₃Leu₁₉₁ evolved from the gene Ala₁₅₃Leu₁₉₁. Alternatively, it may correspond to the Inv(-1, -2, -3) serum reported by Steinberg *et al.*⁹

TABLE 1 Inv phenotype and κ chain structure

Inv	Residue	
	153	191
1, 2, -3	Ala	Leu
-1, -2, 3	Ala	Val
1, -2, -3	Val	Leu
?	Val	Val

All primates tested by van Loghem¹⁰ were Inv(-1, -2). Alepa and Terry¹¹ found polymorphism for both Inv(1) and Inv(3) in chimpanzees. Inv(1) has been found in baboons¹². Neither Inv(1) nor Inv(2) has been found in other monkeys. At present it is difficult to assert the evolutionary relationship between these different genes.

No allotypes in human λ chains have been described but isotypic changes have been reported in protein Kern at position 153 (ref. 13) and in the Oz locus at position 190 (ref. 14). These changes are under the control of non-allelic structural genes. The striking similarity in the location of the changes in the C region of the λ and κ chains probably means that these positions are more likely to undergo changes. Poljak *et al.*¹⁵ and Schiffer *et al.*¹⁶ have built crystallographic models of a Fab' fragment of a human immunoglobulin, New, and a Bence Jones protein respectively. In both cases it has been observed that both positions 152 and 190 occur very loosely in space. The light chain of both proteins is of the λ type but it seems likely that the tertiary structure of κ chains will be very similar if not identical to that of the λ chains. From a 2A crystallographic model (R. J. Poljak, personal communication) of the Fab' fragment of protein New it is possible to see that the positions of the λ chain, equivalent to

153 and 191 in κ chains are located on the surface of adjacent loops, exposed and at a distance of less than 10Å. Furthermore the orientation of the residues is such as to render them accessible to solvent and reagents. Our data indicate that the antiserum Inv(2) recognises leucine at position 191 encompassing position 153. The crystallographic data makes this interpretation acceptable. When position 153, alanine, is replaced by a bulkier amino acid, valine, the Inv(2) reagent is sterically hindered and cannot recognise leucine 191. Antiserum Inv(1) probably does not encompass position 153 and therefore does not distinguish the valine/alanine substitution.

Effect of 5-fluorouracil on the gibberellic acid-induced formation of thermolabile α -amylase molecules in barley aleurone cells

In the aleurone cells of barley seed gibberellic acid (GA) stimulates *de novo* synthesis of α -amylase^{1,2}. From a study of the effect of 5-fluorouracil (FU) on the GA-evoked formation of thermolabile α -amylase molecules, Carlson³ has concluded that GA regulates a post-transcriptional control point. According to my interpretation, which differs from Carlson's conclusion, his data (Fig. 1, ref. 3) suggest that mRNAs for α -amylase are formed in the presence of GA.

Results of studies⁴⁻⁷ of nucleic acid metabolism are consistent with the concept¹ that the formation of α -amylase depends on specific RNA synthesis. Zwar and Jacobsen⁷ confirmed the finding⁵ that messenger-like RNAs are synthesised in tissue treated with GA. Other results suggest a close correlation of the synthesis of α -amylase with this effect of GA, as well as with modifications in RNA synthesis⁸ and the conversion of monosomes to polysomes⁹. Unlike actinomycin D, fluorouracil does not affect the total amount of α -amylase produced by aleurone cells incubated with GA⁷; it does not inhibit the formation of mRNAs⁷, nor does it affect the percentage of polysomes⁹ in the cells. The observed⁷ inhibition of rRNA and tRNA synthesis in aleurone cells is consistent with similar inhibitory effects of the analogue in other tissue¹⁰.

Jacobsen *et al.*¹¹ found that α -amylase produced by GA-treated aleurone cells consist of at least four isoenzymes: 3 and 4 are rendered inactive, while 1 and 2 are stable to treatment with EDTA and sodium metahephosphate. Isoenzymes 1 and 2 represent 20-25% total α -amylase activity. Calcium is an integral part of all four isoenzymes and 1 and 2 are thought to bind Ca²⁺ very strongly. Carlson³ found that when Ca²⁺ was removed from purified α -amylase (presumably from isoenzymes 3 and 4 only) the thermolability (denaturation at 72° C followed by renaturation with addition of Ca²⁺) of the enzyme formed in the presence of FU was greater than that of the 'native' (without FU) enzyme. The thermolability curves (Fig. 1, ref. 3) show that the percentage of thermolabile α -amylase molecules in the purified preparations either increased or decreased depending on whether the tissue was incubated with FU before or after the addition of GA. For example, the data (Fig. 1, ref. 3) obtained when the preparations were subjected to 72° C for 15 min show that 91% of the enzyme molecules produced by the tissue treated with FU for 72 h were thermolabile (Table 1b). Under identical conditions of denaturation 60% of the native enzyme (Table 1a) was also thermolabile. Carlson³ assumed that the thermolability of the α -amylase resulted from a misreading of the FU-containing RNA templates. Consequently, the enzyme preparations were expected to contain, in addition to normal molecules, thermolabile molecules formed on FU:RNA templates. Therefore, the change in the time (min) required to inactivate 50% of the enzyme (T50%) is also a measure of the increase or decrease in thermolabile enzyme molecules in the preparations. Table 1 shows that the T50% of the native α -amylase molecules decreased from 12 to 5 min when the enzyme molecules were formed by tissue incubated with FU continuously for 72 h. These findings raise the question of whether FU:RNA templates for synthesis of α -amylase are formed before or after addition of GA.

Since the tissue treated with FU for 72 h produced 91% labile enzymes, 83-85% of the molecules were formed on FU:RNA templates made by the tissue incubated with GA and FU together for 24 h (Table 1d and f). The data from the reciprocal experiment (Table 1c and e), in which the tissues preincubated (no GA) with 10⁻⁴ FU for 24 and

32 h respectively, produced 70 and 76% thermolabile α -amylase molecules, suggests that the FU:RNA templates were formed before the addition of GA. These tissues were preincubated in the presence of 2.5×10^{-4} uracil, which decreased the percentage of thermolabile molecules from 83 to 76% in 24 h and from 85 to 70% in 32 h. An 8-h pulse of uracil given to a tissue preincubated with FU for 24 h dilutes the pool of analogue (U:FU ratio increases from 4.7 to 77.0) and increases the FU-containing acid-insoluble RNA species⁸.

TABLE 1 Effect of 5-fluorouracil on percentage of thermolabile α -amylase molecules produced by GA-treated aleurone cells

Treatments	Thermolabile enzyme (%)	T50%
(a) Control (no FU)	60	12.0
(b) FU present for 48 h before and during the 24 h treatment with GA	91	5.0
(c) FU present for 24 h before, U present during the 24 h treatment with GA	76	5.5
(d) FU present for 24 h with GA	83	5.0
(e) FU present from 32 to 8 h before GA application, U present during 24 h treatment with GA	70	8.0
(f) FU present for 8 h before, and during 24 h treatment with GA	85	5.0

The percentage of enzyme activity that was stable on heating the EDTA-sodium metaphosphate-treated enzyme preparations at 72°C for 15 min was obtained from Fig. 1, ref. 3. The T50% value, obtained by line intercept of the thermolability curves (Fig. 1, ref. 3) represents the approximate time (min) required to inactivate 50% of the enzyme activity at 72°C. Experimental details are described in ref. 3.

Does the increase in FU-containing RNA species represent the formation of FU:RNA templates? The mRNA is a very small percentage (about 1%) of the total cellular RNA⁷. Although FU inhibits (about 50%) the synthesis of ribosomal and tRNA, it has no effect on the formation of mRNAs or on the total α -amylase produced by the GA-treated cells⁷. α -Amylase is only one of many hydrolases produced by the aleurone cells treated with GA. Time course studies have revealed an actinomycin D-sensitive phase before the formation of α -amylase^{1,12} and protease¹³. The decrease in the percentage lability (from 85 to 70%) and the increase in the T50% value (from 5 to 8 min) resulting from the addition of uracil therefore suggests that enzyme molecules similar in properties to the native enzymes (thermolability 60%, T50% 12 min) are formed in the presence of uracil and after the addition of GA. Since the tissue incubated with FU and GA together for 24 h produced 83% thermolabile molecules compared with 91% in the controls (FU for 72 h), the 'logical' conclusion is that specific FU:RNA templates for the synthesis of thermolabile α -amylase molecules are formed after addition of GA.

In the absence of statistical data (Fig. 1, ref. 3), the differences in the percentage thermolability of the different enzyme preparations (Table 1) are difficult to assess. The decrease in the time required to inactivate thermally 50% of the enzyme molecules as a result of incubation with FU and GA together (Table 1b, d and f), suggests that the FU-containing RNA templates for the synthesis of thermolabile α -amylase molecules are formed after addition of GA. The validity of such a conclusion is based on the assumption that FU:RNA templates allow for the formation of thermolabile enzymes which are otherwise identical in isoenzyme composition, Ca²⁺ binding and other properties to the native molecules. Carlson's discovery³ that FU allows the formation of thermolabile α -amylase molecules, and the finding⁸ that

alterations in nucleic acid methylation prevent enzyme formation, support the suggestion¹⁴ that in the aleurone cells the action of GA involves specific structural modifications of the transcribed substance(s) (RNAs), and consequently a translational modulation of protein synthesis.

Intensity Fluctuation Spectroscopy of Motile Microorganisms

LIGHT microscopy indicates that in *Escherichia coli* translational motility ('running') is accompanied by considerable side-to-side or wobble motion. Moreover, in the case of chemotactic strains Berg and Brown¹ showed that a typical bacterium spends considerable time in a 'twiddling' state in which translation ceases in favour of jittering rotational motion. In both the running and twiddling state the amplitude of the non-translational component of motion is comparable with λ , the wavelength of light. It is reasonable to expect therefore that the dynamics of both wobble and twiddle motion can be studied by intensity fluctuation spectroscopy² (IFS) of scattered laser light. We have examined the effects of wobble motion on the time dependence of the fluctuating light intensity scattered by a non-chemotactic mutant of *E. coli* whose motion is dominated by running with almost no twiddling. We conclude that IFS is sensitive primarily to the rotational component of the motion.

Nossal³ has demonstrated theoretically that under certain conditions IFS is sensitive to the distribution of translational swimming speeds for motile microorganisms. These conditions are: (a) that the particles swim at a constant speed for distances not less than λ ; (b) that the amplitude of non-translational motion is small compared with λ , and (c) that the particles are small compared with λ and (or) spherically symmetric. Although Nossal *et al.*⁴ presented experimental evidence that these assumptions are met in wild type *E. coli*, Schaefer⁵ was unable to reproduce these results, attributing the discrepancies to wobble motion superimposed on translation. Nossal and Chen⁶ subsequently studied the dependence

of motility of *E. coli* on chemoattractant concentration. They assumed that reasonably accurate mean-square translational speeds can be obtained from the initial decay of the intensity correlation function of the scattered light intensity.

In this article we establish the importance of rotational motion by two lines of evidence. First, we discuss a theoretical model in which motility is modelled as a form of uniform helical motion. This is applied to IFS data obtained on a non-chemotactic mutant of *E. coli* (*cheC497*) whose motion seems to be uniformly helical under most conditions (this type of helical motion would appear as side-to-side wobble under a microscope). Although the model is too restrictive for quantitative application, it establishes that IFS is relatively insensitive to the translation swimming speed of *E. coli*. This has been confirmed under viscosity conditions such that wobble motion is suppressed.

A bacterium is considered here to be rod-shaped with length b and negligible width. The body is presumed to simultaneously spin and translate, the body fixed at an angle α with respect to the direction of translation (x axis in Fig. 1). The

Fig. 1 Coordinate system used in model calculations.

body rotates about the translation direction with a single frequency Ω ; $\xi(t) = \Omega t$, where t is time. The intersection of the body axis (σ) and the translation axis is a distance w from the posterior (or equivalently anterior) end of the bacterium.

We make two important assumptions. First, rotational and translational motion are uncorrelated. Although this is not so for helical motion, expansion of the intensity correlation function about $t=0$ indicates that the result obtained below is similar to that expected for correlated motion. Second, to retain tractable equations it is necessary to neglect interference of light scattered from different parts of the same particle. This assumption is sufficiently restrictive that, for asymmetric bacteria, the results can only be used to demonstrate the relative importance of rotational and translational motion.

Within the framework of our model, $R_E(t)$, the correlation function of the scattered light field, takes the following form:

$$R_E(t) = \langle \exp\{i\mathbf{K} \cdot [\mathbf{R}(t) - \mathbf{R}(0)]\} \rangle \left[\frac{1}{b} \int_w^{b+w} d\sigma \langle \exp\{i\mathbf{K} \cdot [\sigma(t) - \sigma(0)]\} \rangle \right] \quad (1)$$

The corner bracket indicates an ensemble average. For incident light of wave vector of magnitude K_0 , $K = 2K_0 \sin \Theta/2$, where Θ is the scattering angle. \mathbf{R} is the position of the intersection of the body axis and the translation axis and σ is the position of the scattering element relative to \mathbf{R} .

If angular and translational motion is uniform for distances large compared with K^{-1} then equation (1) reduces to

$$R_E(t) = [1/4\pi b] \int_w^{b+w} d\sigma \int_0^{2\pi} d\phi \int_0^\pi d\theta \sin \theta \exp[2iK\sigma \sin \phi \sin \theta \sin \alpha \sin(\Omega t/2)] \times \int_0^\infty dV_x [\sin(KV_x t)/KV_x t] P(V_x) \quad (2)$$

where θ and ϕ are the polar and azimuthal angles of \mathbf{K} with respect to the x axis. $P(V_x)$ is the swimming speed distribution, V_x being the projection of the centre-of-mass velocity on the translation axis. For $t \ll \Omega^{-1}$,

$$R_E(t) = \frac{Si[K(b+w)\Omega t \sin \alpha] - Si[Kw\Omega t \sin \alpha]}{Kb\Omega t \sin \alpha} \times \frac{Si(KV_m t)}{KV_m t} \quad (3)$$

where Si is the tabulated sine integral⁷. In deriving equation (3) $P(V_x)$ has been assumed to be uniform up to a maximum speed V_m (the final results are insensitive to this distribution). Since $(b+w)\Omega \sin \alpha$ is the speed of the tip of the spinning organism, the rotation factor of equation (3) will be important whenever the tip speed is comparable with or greater than V_m .

Several observations are pertinent to equation (3). First, measured correlation functions should scale when plotted as a function of Kt if the assumptions of our model are met. Second, breakdown of Kt scaling indicates either high rotational frequencies, nonuniform motion over distances of the order of K^{-1} , or possibly particle asymmetry. Third, $R_i(K, t)$, the experimentally measured photocurrent correlation function, is proportional to the intensity correlation function rather than the field correlation function. The time-dependent part of $R_i(K, t)$, however, is proportional to $|R_E(t)|^2$ so that experimental data are compared with the square of equation (3).

Our experimental work involved measurement of the $R_i(K, t)$ for light scattered from a non-chemotactic strain of *E. coli* (*cheC497*)^{1,8}. The bacteria were studied under viscosity conditions conducive to both normal motility (showing significant non-translational motion) and motility in which the amplitude of off-axis motion was suppressed. In either case, motility in *cheC497* is dominated by running with little twiddling¹.

Samples were grown and studied in closed tubes containing Hutner's medium + 0.5% dextrose⁹. Samples were grown initially at 22° C and then at 30° C for at least three generations. All results were obtained at 30° C during the stationary phase, when the decay time of $R_i(K, t)$ showed a broad (1–3 h) minimum. We used high density populations (absorbance ~0.5) to avoid complications due to fluctuations in the total number of bacteria in the scattering volume^{5,10}. The incident wavelength was 6,328 Å and the experiments were performed with a SAICOR 43A correlator. A dilution experiment was performed as a control. A typical sample was diluted by a factor of four with air-saturated distilled water. No immediate change was observed in $R_i(K, t)$, suggesting that neither interparticle interactions nor small changes in oxygen concentration significantly affected our results.

The bacteria were also observed by light microscopy. Wobble motion with $\langle \alpha \rangle \sim 35^\circ$ was observed during all phases of growth (except in solutions containing Methocel). We tried to determine $\langle \Omega \rangle$ using stroboscopic illumination. Although high translational speeds precluded accurate measurement of $\langle \Omega \rangle$, angular velocities exceeding 10^2 rad s⁻¹ were observed for certain individuals.

Figure 2 shows $R_i(K, t)$, the measured photocurrent correlation function, at several scattering angles for samples in culture medium (viscosity = 0.82 cP at 30° C). The very short characteristic times of these curves indicate that the decay

Fig. 2 Measured photocurrent correlation for light scattered from *E. coli cheC497* at $\Theta=20^\circ, 35^\circ, 50^\circ, 70^\circ, 90^\circ$ (solid lines) compared with calculated curves for pure translation (squares, $\alpha=0$, $V_m=50 \mu\text{m s}^{-1}$) and helical motion (crosses, $\alpha=35^\circ$, $b=2.7 \mu\text{m}$, $w=0.3 \mu\text{m}$, $\Omega=60 \text{ rad s}^{-1}$, $V_m=50 \mu\text{m s}^{-1}$).

was not caused by translational motion since analysis based on a pure translational model ($\alpha=0$) yields average speeds of more than $100 \mu\text{m s}^{-1}$, which are unreasonably large. Also, Kt scaling predicted by equation (3) was observed. This scaling was not observed for scattering angles larger than 90° or for other strains of *E. coli*.

Two theoretical curves are presented in Fig. 2. The squares represent the square of equation (3) assuming rectilinear motion ($\alpha=0$) and the crosses are calculated for helical motion with $b=2.7 \mu\text{m}$, $w=0.3 \mu\text{m}$, $\alpha=35^\circ$, $\Omega=60 \text{ rad s}^{-1}$ and $V_m=50 \mu\text{m s}^{-1}$. Although our theory is not expected to predict the curvature, a comparison of the characteristic times of these curves indicates the dominance of non-translational motion. The significance of Kt scaling displayed by these data cannot be established by reference to equation (3), due to the neglect of intraparticle interference.

Fig. 3 Comparison of photocurrent correlation function of light scattered from *E. coli cheC497* at different solution viscosities. Data were taken at 30°C with $\Theta=70^\circ$. Upper curve, 1.6 cP; lower curve, 0.8 cP.

The most conclusive evidence for the importance of rotational motion was established by comparison of data taken from different solution viscosities. Figure 3 shows $R_1(K, t)$ for light scattered at 70° scattering angle from samples grown in the culture medium and in this medium plus 0.2% hydroxypropyl methyl cellulose (Dow Methocel 90 HG, viscosity 1.6 cP at 30°C). In the latter medium the translational speed is 20% greater, and the wobble motion is almost completely suppressed¹¹. Thus, if translation were dominating the decay of $R_1(K, t)$ a shorter characteristic time would be observed in 0.2% Methocel. In fact, a considerably longer characteristic time is found consistent with the decreased amplitude of off-axis motion ($\langle \alpha \rangle$ smaller). This establishes the dominance of non-translational motion at low viscosities. Considerable variability ($\pm 20\%$), was observed for the decay times in 0.2% Methocel, making it difficult to establish whether Kt scaling was observed.

Our results contrast with those obtained by Nossal *et al.*^{4,6} who were able to grow non-rotating cultures. We were unable successfully to repeat their experiments because (a) cultures showed great variability when collected in the log phase; (b) centrifugation led to greatly increased correlation times due to non-swimming bacteria; (c) number fluctuations¹⁰ often obscured the results at low population densities, and (d) cultures grown below 30°C had noticeable numbers of non-swimming bacteria.

We conclude that in most cases IFS is not directly sensitive to the translational speed of motile microorganisms such as *E. coli*. Although this diminishes the utility of IFS for study of centre-of-mass motion, it facilitates study of rotational motion, which is important in the understanding of flagellar action¹¹ and chemotaxis^{1,12}. Furthermore, since rotational frequencies are likely to scale with translation speed for a given solution viscosity, IFS can still be used to study the effects of environmental parameters (temperature, chemo-attractant concentration⁶) on swimming speeds.

We thank H. C. Berg for this mutant. We also thank him and R. A. Anderson for discussions. We thank J. P. Boon, R. Nossal and S.-H. Chen for communicating an unpublished manuscript. This research was supported by the US Atomic Energy Commission and by a grant from the National Science Foundation.

Is craniofacial asymmetry and adaptation for masticatory function an evolutionary process?

MANY workers have investigated asymmetry of primate skulls. Woo¹ carried out direct chordal and arcual measurement on a large number of human skulls from the 26th to the 30th Egyptian dynasties. He found the bones of the cranium exhibited an asymmetry with the right side being larger, reflecting the development of the right hemisphere of the brain. The contralateral side of the facial complex exhibited an asymmetry with the left zygoma and left maxilla being larger. The lower third of the face was not investigated.

Mulick² investigated human facial asymmetry using cephalometric skull radiographs with a three-dimensional grid system of analysis and reported a facial asymmetry in six same-sex triplets, with the larger side being to the left.

Groves and Humphrey³ reported an asymmetry of gorilla skulls (*Gorilla gorilla beringei*) with the left side exhibiting a marked increase in length from the temporal fossa to the gnathion. They postulated that such asymmetry may be consequent to an asymmetry of function of the masticatory system.

The skull complex consists of numerous constituent parts. It is, therefore, the degree of harmony between the parts which determines the symmetry of the whole. The following investigation into human facial asymmetry was devised to establish a method for analysis of overall facial asymmetry in terms of its component parts, each of which can individually vary between the right and left sides.

Sixty posterior-anterior cephalometric skull radiographs of normal children were traced. No child with a degree of clinically evident or unacceptable facial asymmetry or gross deviation of dental arrangements was included.

Six bilateral and four single roentgenographic landmarks were delineated. The single landmarks were: sella; anterior nasal spine; incisal point; menton. The bilateral landmarks were: orbitale; centre of condylar shadow; zygomatic point; upper molar point; gonion; superior extent of condyle.

To assess the relative asymmetry of the component parts of the facial complex, a method of triangulation was used. The roentgenographic landmarks were joined to form triangles on both sides of the midline, representing the right and left mandibular regions, lower, middle and upper maxillary areas and the cranial base regions. The sides of the triangles were measured to the nearest 0.5 mm. and the areas compared with the areas of the equivalent triangles of the contralateral side.

The investigation revealed an overall asymmetry in most cases with the larger side to the left. The cranial base region, lower maxillary region and mandibular region exhibit a left sided excess. The maxillary region showed a right sided excess and the dento-alveolar region the greatest degree of symmetry.

The findings are of interest in that they suggest a compensatory adaptation during growth to effect an integration of the facial components. Scott⁴ suggested that the facial skeleton should be considered as a unit built up of a number of semi-independent regions, each with its own pattern of growth and development. The orbits, nasal cavities and lower border of the mandible show a high degree of independence and are under genetic control in their determination with the dento-alveolar region and lower parts of the nasal cavities showing a greater response to functional variation. These suggestions may be supported by the present findings. The mechanism whereby this occurs may be part of an evolutionary process. Adaptation of the dento-alveolar structures to muscle pressures is well recognised.

It is reasonable to assume that optimal function is provided by maximum cuspal interdigitation of teeth. We accept that this relationship can be arrived at in occlusion (that is, with

the teeth together) even though facial asymmetry may still exist. If in the rest position, or in the habitual postural position of the mandible, the upper and lower teeth are not co-incident about the sagittal plane, then an asymmetrical functional activity of both temporomandibular joint mechanisms must compensate during chewing and non-chewing activities in which the teeth are approximated. This in clinical practice is frequently related to pain and dysfunction and is therefore not a normal adaptation in humans.

To enable bilaterally symmetrical function and maximum intercuspation of the teeth to occur, compensatory changes seem to be operating in man in the growth and development of the dento-alveolar structures which minimise the underlying asymmetry in the spatial arrangement and size of the jaws.

This factor whilst no longer being essential for man's survival with his modern diet may nevertheless be regarded as a possible factor in the evolution and natural selection processes of the subhuman species.

Deltatheridium and Marsupials

THE evidence for the radical transfer of the famous genus *Deltatheridium* to the Marsupialia seems to be partly different from that already presented¹. The cheek tooth formula, a key character separating marsupials and placentals, is questionable for *Deltatheridium*. There are seven cheek teeth, as usual in both groups, and the fourth is molariform, as in marsupials. This is evidence on phyletic affinity only if the primitive state, that of the latest common ancestor, was otherwise. In a manuscript that has circulated privately since 1963 I have argued from diverse evidence that the seven cheek teeth of each group may well be directly homologous with those of the other, with an ambiguity as to the permanent or deciduous premolars. In other words, P₄ or DP₄ of placentals may well be homologous to M₁ of marsupials. If so, a more or less molariform state of the fourth cheek tooth is primitive to both groups and the often nonmolariform state in more or less primitive placentals is secondary. This was why I suggested² that *Deltatheridium* might have one more molar than previously thought; the suggestion is now confirmed. Relative wear of the teeth is a useful but unreliable criterion (ref. 3, footnote on page 86).

Positive evidence, however, comes from the fact that there is a sharp morphological break between the third and fourth cheek teeth. This is characteristic of marsupials but not of primitive placentals or the pantothere quasi-ancestor of both groups, *Peramus*⁴.

If *Deltatheridium* is a marsupial, as seems entirely possible, it is specially similar only to the Stagodontidae^{5,6} among possible relatives. Butler and Kielan-Jaworowska ascribe this similarity to parallelism, but there seems no positive evidence of such. Normal marsupial styler cusps are retained in *Didelphodon* but not *Deltatheridium*, so some divergence is indicated. I prefer to classify the ancestors of marsupials and placentals as marsupials, which increases the probability of allocation of *Deltatheridium* to marsupials without affecting the phyletic evidence.

It should be noted that some time ago⁷ I abandoned my ordinal name, *Deltatheridia*⁸ (I now use *Hyaenodonta*), without change in the phyletic and adaptive evidence^{3,9,10} used to establish the order. Dr Kielan-Jaworowska showed me her new material on a recent visit but my comments are based on the published data.

Temperature-sensitive mutations affecting the regenerative sodium channel in *Drosophila melanogaster*

IN an attempt to elucidate the functions of the nervous system using behavioural mutants of *Drosophila melanogaster*, several sex-linked temperature-sensitive paralysis mutants have been isolated^{1,2}. These mutants are reversibly paralysed at 29° C while remaining normal at 22° C. The author set out to determine the molecular basis for the paralysis in one allelic series of these mutants, *shibire* temperature-sensitive (*shi*^{ts})².

A number of pharmacological agents are available which block particular functions of the nervous system. Here I report the effect of one such agent, tetrodotoxin (TTX), on the *shi*^{ts} mutants. This toxin is known to specifically block the regenerative sodium channel of the action potential mechanism³.

Varying concentrations of TTX in 0.05 M citrate buffer pH 4.8 were fed to wild-type and *shi*^{ts} flies at 22° C. After 20 h, these flies were transferred to vials containing fresh food and 12 h later the number of live and dead flies was counted. In this way, kill curves were determined for the allele *shi*^{ts} and wild-type Oregon-R flies. The 12 h delay prior to scoring allowed those flies which were initially debilitated by the treatment to either recover or die. In most cases, debilitated flies recovered during this interval and so only two classes of fly were counted, dead or alive. The kill curves obtained for these two strains are shown in Fig. 1. The *shi*^{ts} flies are far more resistant to TTX than their wild-type counterparts, the LD₅₀ of *shi*^{ts} being three times greater than that of the wild-type strain.

To show that the result observed was due to the mutation at the *shi* locus and not just the genetic background of this strain, all of the other five *shi*^{ts} alleles² were tested for their resistance to the toxin. Table 1 shows the effect of feeding TTX at a concentration of 5 µg ml⁻¹ to flies carrying each of the *shi*^{ts} alleles and including a wild-type control. As might have been expected, the alleles defined as more extreme², *shi*^{ts1} and *shi*^{ts2}, conferred the greatest resistance while the least extreme alleles, *shi*^{ts4} and *shi*^{ts5}, exhibited very little resistance. Two unexpected results were that *shi*^{ts3}, an allele with an intermediate paralytic phenotype, was more resistant to TTX than *shi*^{ts1}, and *shi*^{ts6}, which is

Fig. 1 Effect of increasing concentrations of TTX in 0.05 M citrate buffer pH 4.8, on a, Oregon-R, and b, *shi*^{ts} flies at 22° C. Incubation time was 20 h. Each point represents ten vials, each vial containing fifty flies. For either *shi*^{ts} or Oregon-R flies the variation in kill between vials at the same TTX concentration was always less than 5%. Arrows marked a and b indicate LD₅₀ for Oregon-R and *shi*^{ts} flies respectively.

normally considered a strong allele, was the least resistant. Other studies on the paralysis and lethality of various heterozygous combinations of the *shi*^{ts} alleles have, however, shown that in *shi*^{ts1}/*shi*^{ts1} heterozygotes, the *shi*^{ts1} phenotype is expressed while in *shi*^{ts1}/*shi*^{ts2} flies, the *shi*^{ts2} phenotype is dominant (T. C. Kaufman and D. T. Suzuki, in preparation). In fact, *shi*^{ts5} and *shi*^{ts6} are recessive to all of the other *shi*^{ts} alleles. Furthermore, *shi*^{ts1} and *shi*^{ts2} are the only alleles which are viable in heterozygotes carrying a deficiency for the *shi* locus (T. C. Kaufman and D. T. Suzuki, in preparation). Thus, the sensitivity to TTX suggests a difference in properties of *shi*^{ts1} and *shi*^{ts2} which are corroborated by other criteria.

TABLE 1 Effect of TTX on *shi*^{ts} Alleles

Genotype	No. of flies		% kill
	Dead	Alive	
Oregon-R	300	11	96.5
<i>shi</i> ^{ts1}	188	284	39.8
<i>shi</i> ^{ts2}	156	344	31.2
<i>shi</i> ^{ts3}	210	285	42.5
<i>shi</i> ^{ts4}	308	184	62.6
<i>shi</i> ^{ts5}	298	190	61.1
<i>shi</i> ^{ts6}	392	103	79.1

5 µg ml⁻¹ TTX was used on mixed male/female populations. No preferential killing of males or females was observed.

Heterozygous *shi*^{ts}/+ flies have also been tested for their TTX resistance. Table 2 shows the effect of 5 µg ml⁻¹ of TTX on these flies as compared to *shi*^{ts1}/*shi*^{ts1} and wild-type females. The TTX resistance of these heterozygous flies was found to be intermediate in value, being less than *shi*^{ts1} but greater than Oregon-R. This result correlates with the semi-dominant paralytic characteristics of *shi*^{ts}, in that *shi*^{ts}/+ heterozygotes are immobilised at 35° C but not at 29° C (L. E. Kelly, L. Hall, and D. T. Suzuki, in preparation).

It could be suggested that the resistance of *shi*^{ts} flies to TTX is simply a reflection of the difference in either their drinking behaviour or their ability to absorb the toxin through the gut wall. Consequently, the following experiment was performed. Bilateral mosaics were recovered from a cross of *shi*^{ts} males to females carrying an unstable ring X chromosome (*In(1)w^{sc}*)⁴. Loss of this ring X chromosome shortly after

TABLE 2 Effect of $5 \mu\text{g ml}^{-1}$ TTX on heterozygous *shi^{ts1}/+* females

Genotype	No. of flies		
	Dead	Alive	% kill
Oregon-R	14	212	93.8
<i>shi^{ts1}/shi^{ts1}</i>	176	63	26.3
<i>shi^{ts1}/+</i>	143	104	41.7

Controls were female. (The difference between the kill of *shi^{ts1}* females in this experiment and that shown in Fig. 1 is probably due to the use of a new batch of TTX for this experiment.)

fertilisation produces flies which contain cells which are heterozygous, *shi^{ts1}/+*, and hemizygous, *shi^{ts1}/0*, for the *shi^{ts1}* mutation. A mutation conferring yellow body colour was linked to the *shi^{ts1}*-bearing chromosome so that the genotype of the cells in the external chitin could be determined. Bilateral mosaics produced in this fashion have one side which is female and heterozygous for *shi^{ts1}* and the other side is yellow, male and genotypically *shi^{ts1}/0*. When shifted to 29°C , the *shi^{ts1}/0* half of the bilateral mosaic became paralysed, while the *shi^{ts1}/+* half remained normal. It has already been shown (Table 2) that *shi^{ts1}/+* flies are less resistant to TTX than hemizygous *shi^{ts1}/Y* flies. If, however, the resistance of *shi^{ts1}* flies to TTX was due solely to a reduction in the uptake of the drug, the haemolymph of the bilateral mosaic would be expected to contain a uniform distribution of TTX so that both halves of the animal would be equally affected. The bilateral mosaics were fed TTX at a concentration of $10 \mu\text{g ml}^{-1}$ for 10 h. These conditions had previously been found to severely debilitate a population of *shi^{ts1}/+* heterozygotes without causing much death. In the mosaics so treated, the *shi^{ts1}/+* sides of the flies were debilitated as expected; however, the *shi^{ts1}/0* halves of the same animals remained unaffected. Thus, the debilitation of the mosaics after TTX feeding was the reverse of the paralytic effects observed when the mosaics were shifted to 29°C . This result shows that the difference in resistance between *shi^{ts1}* and wild-type to TTX is not due to a difference in the uptake of the toxin; rather, the *shi^{ts1}* tissue is indeed resistant to the molecule.

Although the neurophysiological effect of TTX is known, there is still the possibility that the TTX-induced lethality in *Drosophila* is not due to a malfunctioning of the nervous system, but to some secondary toxic effect of the drug. To eliminate this latter possibility, it is necessary to show some TTX resistance of *shi^{ts1}* flies in neurophysiological terms. This was done by comparing the effect of a controlled dose of TTX on the electroretinogram (ERG) of *shi^{ts1}* and Oregon-R flies. TTX eliminates the 'on' and 'off' transients of the d.c. recorded ERG of wild-type *Drosophila* (Fig. 2). The heads of ten *shi^{ts1}* and ten Oregon-R flies were each injected with $0.1 \mu\text{l}$ of a $25 \mu\text{g ml}^{-1}$ solution of TTX in 0.6% NaCl and the ERGs were recorded. Within 5 min, nine out of the ten wild-type flies produced an ERG which did not possess the transients, while all ten of the *shi^{ts1}* flies retained the transients for longer than 30 min after the injection. While it cannot be said that each injected head retained all of the TTX, the result does indicate that those cells which give rise to these transients are more sensitive to TTX in Oregon-R flies as compared to the same cells in *shi^{ts1}* flies. It can be concluded from this experiment that the resistance to TTX which is conferred by the presence of the *shi^{ts1}* allele reflects an altered sensitivity of the nervous system to the toxin.

Since the *shi^{ts1}* alleles cause temperature-sensitive paralysis, it might be expected that the TTX resistance would also show a temperature dependence. As *shi^{ts1}* flies become paralysed when kept at temperatures in excess of 25°C for prolonged periods and as it has been found that 18°C rather

Fig. 2 Effect of TTX on the ERG of wild-type *Drosophila*. A, Normal ERG of a wild-type fly. Note the presence of the 'on' transient (a) and the 'off' transient (b). B, ERG from a wild-type fly injected with $0.01 \mu\text{l}$ of a $100 \mu\text{g ml}^{-1}$ solution of TTX in 0.6% NaCl. Note the loss of the transients.

than 22°C is the true permissive temperature for *shi^{ts1}* (L. E. Kelly, L. Hall, and D. T. Suzuki, in preparation), the resistance of *shi^{ts1}* to TTX at 17°C and 22°C was compared. Kill curves were constructed for *shi^{ts1}* and Oregon-R at 17°C . As both strains seemed however to be more resistant to TTX at this temperature, the incubation time was extended to 48 h. This produced a kill curve for Oregon-R which is comparable to that obtained at 22°C . The curves obtained (Fig. 3) show that there is a large increase in the resistance of *shi^{ts1}* to TTX at this temperature, the LD_{50} of *shi^{ts1}* being some seven times greater than wild type. Preliminary investigations of *shi^{ts1}* flies at 22°C and 25°C indicate that *shi^{ts1}* is also more resistant at the lower temperature. Finally, if the *shi^{ts1}* flies are fed TTX at 22°C to the point of debilitation and then shifted down to 17°C , they recover from the debilitation

within 5 min, while no comparable effect is observed with Oregon-R flies. The converse is also true; *shi¹¹¹* flies which are debilitated by TTX at 17° C are immediately paralysed and die when shifted to 22° C. This indicates two things; first, the debilitation induced by TTX is temperature reversible in *shi¹¹¹* and secondly, the increased resistance of Oregon-R and, in part, of *shi¹¹¹* at 17° C is probably due to a reduced rate of uptake of liquid in both strains. This may be a consequence of reduced dehydration at the lower temperature.

Fig. 3 Effect of increasing concentrations of TTX on a, Oregon-R, and b, *shi¹¹¹* flies at 17° C. Incubation time was 48 h. Arrows marked a and b indicate LD₅₀ for Oregon-R and *shi¹¹¹* flies respectively.

In conclusion, it has been shown that the *shi¹¹¹* alleles confer on *Drosophila* a resistance to TTX which, like the paralysis of these flies, is temperature dependent. It has also been demonstrated that this resistance is attributable to an alteration in the properties of the nervous system. The TTX resistance results obtained for the *shi¹¹¹* and *shi¹¹²* alleles are interpreted as resulting from alterations of different sites in the protein molecule encoded by this gene. It is suggested that the *shi¹¹¹* locus is involved in the production of some component of the regenerative sodium channel and that the presence of the *shi¹¹¹* allele, as well as producing temperature-sensitive paralysis, also reduces the affinity of this channel for TTX.

I thank Drs David T. Suzuki and Linda Hall for discussions. This research was supported by grants from the National Research Council of Canada and the National Cancer Institute of Canada to Dr Suzuki.

Dinosaur Monophyly and a New Class of Vertebrates

TRADITIONALLY dinosaurs are classified as two or three separate, independent groups of reptiles in the Subclass Archosauria. But evidence from bone histology, locomotor dynamics, and predator/prey ratios strongly suggest that dinosaurs were endotherms with high aerobic exercise metabolism, physiologically much more like birds and cursorial mammals than any living reptiles¹⁻⁸. Recently Ostrom has argued forcefully that birds are direct descendants of dinosaurs and inherited high exercise metabolism from dinosaurs^{1,8}. Here we present evidence that dinosaurs are a single, monophyletic group, and that the key advancements of endothermy and high exercise metabolism are justification for removing dinosaurs from the Reptilia and placing them with birds in a new class, the Dinosauria.

The two generally accepted orders of dinosaurs, the Saurischia and Ornithischia, are usually interpreted as independent derivatives of primitive thecodontian reptiles of the Triassic, but all known Triassic dinosaurs can be distinguished from typical thecodontians (Fig. 1)⁹⁻²³.

Most thecodontians had a wide-track sprawling gait or a crocodile-like semi-erect gait, both requiring much multidirectional mobility at the shoulder⁶. The thecodontian glenoid, or shoulder socket, was lizard or crocodile-like—being a saddle-shaped notch facing outward and backward, permitting humerus rotation, abduction, and backswing. Dinosaur glenoids were concave sockets facing mostly down and backwards, little outwards, restricting humerus movement severely to a fore-and-aft vertical plane—the 'fully erect gait'⁶.

Also, in thecodontians and reptiles, generally, the deltopectoral crest (*dp* in Fig. 1) is located close to the humerus head, giving the pectoralis musculature good leverage for rotating the humerus about its long axis but relatively little leverage for a vertical humerus backswing. In dinosaurs, the vertical backswing leverage was increased by moving the deltopectoral crest down the humerus shaft (Figs. 1 and 2).

In thecodontians and reptiles generally, the fourth trochanter (*4t* in Fig. 1) usually was located close to the femoral head, giving the caudifemoralis brevis musculature good long-axis rotational leverage, but little leverage for a vertical backswing. In dinosaurs, the apex of the fourth trochanter was developed into a distally directed flange, increasing the leverage for a vertical backswing (Figs 1 and 2).

A sprawling or semi-erect gait directs the thrust of the femur strongly inwards into the acetabulum, or hip socket. The thecodontian acetabulum usually was a strong, continuous bony surface as in most living reptiles. In dinosaurs, femoral action was more restricted to a vertical plane; the acetabulum was perforated to allow deeper penetration of the inturned femoral head, and the weight of the body was transmitted from the proximal surface of the femur to the strong dorsal rim of the acetabulum²⁴.

The thecodontian hand, known in phytosaurs²⁰, aetosaurs^{17,25}, rauisuchids²⁶ and 'Cheirotherium'^{27,28}, was crocodile-like with five long digits, the inner three subparallel, the outer two divergent (Fig. 1). The hand of Triassic saurischian dinosaurs is distinctive (Fig. 1) with a very short, stout metacarpal I; a long, strong thumb phalanx I; a powerful, curved, trenchant thumb claw; thumb articulations forcing the claw to diverge and point inwards during extension, converge with digits II and III and point downwards during flexion; long digits II and III, subequal and subparallel, bearing trenchant claws; and reduced digits IV and V²⁹. The hand of the better known primitive ornithischians (fabrosaurids and hypsilophodontids) differed from that of Triassic saurischians in lacking the long thumb and having blunt hooves instead of claws on digits I to III (ref. 30). Recently, a complete articulated skeleton of *Heterodontosaurus*, a Triassic ornithischian, was collected by A. W. Crompton, now at Harvard, for the South African Museum. The hand is virtually identical to that of

(s) Scapula, (c) coracoid, (dp) deltopectoral crest, (lc) lunate carpal, (il) ilium, (is) ischium, (p) pubis, (a) astragalus, (ca) calcaneum, (ft) femorotibialis, (4t) fourth trochanter, (---) long axis of glenoid.

Triassic saurischians in all six of the features cited above. Although specialised cranially³¹, *Heterodontosaurus* probably represents the original ornithischian hand pattern, inherited from saurischians, where the thumb was specialised for defence and digits II and III were used for defence, digging, and support during slow, quadrupedal locomotion. In more advanced ornithischian hands, the defensive function was lost, the thumb was secondarily shortened and simplified, and the claws were replaced by hooves, but in *Hypsilophodon*, digits II and III are still subequal and subparallel³⁰.

The origin of the femorotibialis, a knee extensor, in most thecodontians and in reptiles generally, is on the smooth anteriolateral surface of the femoral shaft. In primitive saurischians and ornithischians, the origin was expanded by the development of a spike-like ridge (*f.t.* in Fig. 1). In advanced saurischians and ornithischians, and in birds, this spike becomes a large crest—the 'lesser trochanter', not homologous to the lesser trochanter of mammals. Increased muscle power for knee extension probably was related to the development of the fully erect gait. Ornithomimid thecodonts have this crest but differ from dinosaurs dramatically at the ankle and forelimb^{10,18}.

The ankle of most thecodontians was complex and crocodile-like: the astragalus articulated movably with the calcaneum and tibia, and the calcaneum bore a 'heel' (calcaneal tuber) for the gastrocnemius musculature^{24,32}. In advanced thecodontians the astragalus-calcaneal joint was a deep ball and socket³³. In sharp contrast, the dinosaur ankle was stiff, simple and bird-like: the astragalus and calcaneum were rounded caps fixed immovably on the ends of the tibia and fibula; the distal tarsals were immovable caps on the metatarsal heads, and the tarsal joint was a simple unidirectional hinge between astragalus-calcaneum and distant tarsals (Fig. 1)^{24,28}. Saurischian diphyly has been suggested because some theropods, such as *Allosaurus*, have deep ilia and a thin, anterior ascending process of the astragalus, while prosauropods have unexpanded ilia, no ascending process, and a peg-in-notch astragalus-tibial joint^{22,34}. Triassic forms, however, show how the transition from prosauropod-grade to advanced theropod grade saurischian occurred. The Triassic theropods *Syntarsus* and *Halticosaurus* had expanded ilia but retained a prosauropod-type astragalus-tibial joint without an anterior ascending process^{35,36}. In general, the prosauropod grade of postcranial anatomy seems to be the primitive dinosaur pattern. Details of tarsal structure are often obscured by incomplete ossification, but the pattern in *Syntarsus* is virtually identical to that of *Heterodontosaurus* (Fig. 1). Digit I arises two-thirds down the length of metatarsal II and is reduced and slightly divergent; digits II and IV are subequal; digit III is the longest; digit V is reduced to a splint; distal tarsal IV is cuboid; III is rectangular; II is a thin plate and the astragalus-calcaneum are prosauropod-like.

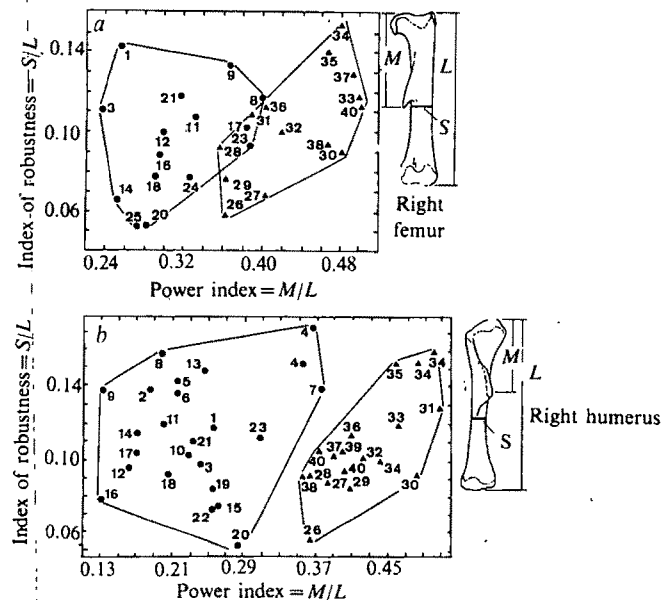

Fig. 2 Robustness and position of muscle attachments, (a) in the femur and, (b) in the humerus. The data are taken from specimens and refs 9, 10, 13, 15–20, 26, 28, 30, 36, 38, 39, 42, 43. (S) Minimum shaft diameter, (L) length of femur or humerus, (M) distance from head to muscle attachment (deltopectoral crest in humerus, fourth trochanter in femur).

The radiations of thecodontians and dinosaurs were based on different trends in locomotor anatomy, behaviour, and exercise metabolism. The earliest thecodontians, the proterosaurs¹⁵, had short limbs and a sprawling posture with a wide range of movement at each joint⁶. Stride length and power in the sprawling gait are increased by vertebral column undulations, and thecodontians generally lack adaptations for inhibiting lateral undulation. The complex ankle of advanced thecodontians was probably a response to selection for finer control of supination-pronation and greater leverage in sprawling locomotion. Thecodontian footprints²⁷ indicate that digit V in the hand and foot were strongly divergent and powerfully muscled, like digit I of climbing mammals. Flexibility at the major limb joints plus divergent digit V probably gave thecodontians a wide locomotor repertoire, including some digging, climbing, and movement over uneven ground. Some of the later Triassic thecodontians (such as aetosaurs and phytosaurs⁶) retained the sprawling gait and others, such as rauisuchids and ornithosuchids^{10,18}, developed a crocodile-like locomotor system which make possible both sprawling and semierect gaits^{6,37}. Inturned femoral heads indicate that a few thecodontians such as *Hallopus* and some advanced rauisuchids and ornithosuchids¹⁹, may have had narrow-tracked, fully erect hindlimbs, but even these forms retained the complex ankle.

The first well-known dinosaur is *Staurikosaurus*, of late Middle or early Late Triassic^{38,39}, a long-jawed predator with very long, gracile hindlimbs and postcranial anatomy of prosauropod grade (the femoral head is not as sharply inturned as in later dinosaurs and there is an oval acetabulum). More advanced theropods, such as *Ischisaurus* and *Herrerasaurus*, and ornithischians, such as *Pisanosaurus*, appear shortly after *Staurikosaurus*⁹. The original dinosaur stock were probably predators with higher running speeds and exercise metabolism than in thecodontians of comparable size. Early dinosaurs may have been dipedal at top speed, but the strong forelimb modifications for the fully erect gait and the prosauropod-like hand indicate that quadrupedal progression was very important. Even at the prosauropod grade, dinosaur bone histology was identical to that of endothermic mammals⁴. Restriction of joint movement to a fore and aft, vertical plane and the stiff, bird-like ankle would have made climbing difficult for any dinosaur⁴⁰. The vertebral column of early dinosaurs was stiffened to inhibit lateral undulations by the development of extra vertebral articulations, the hyposphene-hypantra in saurischians, and long ossified tendons appressed against the neural spines in ornithischians. The locomotor repertoire of dinosaurs was narrow, rather restricted to moving over fairly even terrain. Recent experiments⁴¹ show that erect locomotion does not require less energy for a given speed than sprawling, as has usually been assumed⁶, but erect locomotion probably does increase manoeuvrability at very high speeds. The dinosaur radiation was based on a concentration of behavioural, physiological, and anatomical adaptations for high, sustained running speeds which made them irresistible predators and competitors to contemporary thecodontians and the larger mammal-like reptiles.

Could the similar postcranial adaptations of Triassic dinosaurs reflect merely convergent evolution of the erect gait from different thecodontians? We believe that the answer to this question is almost certainly no. Evolution of erect posture does not invariably lead to an avian-dinosaur type joint pattern. Some thecodonts and many mammals, such as carnivores and ungulates, have a fully erect gait but retain complex ankles with astragalar-calcaneal mobility and calcaneal 'heels'. The very detailed similarity in all the major joints, especially the hands and feet, of Triassic ornithischians and saurischians makes dinosaur polyphyly exceedingly unlikely. Moreover, the pattern of increasing dinosaur diversity in the Triassic upwards from the stratigraphic level of *Staurikosaurus* suggests one monophyletic radiation. Some of the little 'rabbit thecodontians' such as *Lagosuchus* and *Lagerpeton*^{42,43}, have im-

mobile astragalar-calcaneal joints and lack calcaneal 'heels', and may be related in some way to dinosaur origins.

The prosauropod saurischians have a mixture of primitive and advanced features which show how ornithischians evolved from saurischians (Fig. 1). In the primitive ornithischian dentition, represented by *Fabrosaurus*, the anterior teeth were non-serrated, pointed and slightly incurved with swollen bases and the cheek teeth were serrated with triangular crowns⁴⁴. In some prosauropods, such as *Massospondylus* and probably *Anchisaurus*, the basic pattern was similar: anterior, simple teeth and triangular, serrated cheek teeth. In advanced prosauropods, such as *Plateosaurus* and in most ornithischians, the jaw articulation was depressed below the tooth row level, but in *Fabrosaurus* and *Anchisaurus* the articulation was still on the same level as the tooth row⁴⁴. The lower jaw of most ornithischians was deep and massive, but the fabrosaur jaw was slender like that of *Anchisaurus*. In early ornithischians the origin of iliotibialis, a knee extensor co-inserting with the femorotibialis, was expanded by the development of a long anterior iliac prong. Such a prong is unknown in thecodontians and most prosauropods, but is present in very fabrosaur-like configuration in *Anchisaurus* and *Ammosaurus*⁴⁵. In ornithischians the primitively broad, plate-like ventral surface of the pubis and ischium were deeply excavated and reduced; such excavations had begun in the prosauropods *Anchisaurus* and *Ammosaurus*⁴⁵.

The prosauropod grade is quite primitive, and herbivorous prosauropods must have diverged very early from the basal, predatory dinosaur stock. It should be noted that no thecodontians show trends away from carnivory towards herbivory, except the aetosaurs, sprawling, armoured types totally unlike ornithischians¹⁷. Small prosauropods with *Anchisaurus*-type jaw articulations, ilia and pubes were probably the immediate ancestors of ornithischians. The adaptive shift probably was an emphasis on ultra-high speed bipedality plus adaptations for prehension and cutting of plant fibres. Excellent fabrosaur material collected for the South African Museum and now at Harvard, shows that the development of an upper beak had just barely begun in *Fabrosaurus*. The fabrosaur predentary was small, sharply pointed, and movably articulated with the dentary; the dentary symphysis was mobile. The predentary beak could serve as a gouge for digging into plant stems and as a cutting edge occluding with the arcade of premaxillary teeth, much like the incisors of kangaroos⁴⁶, while the mobile symphysis permitted the retention of independent control of each jaw ramus, important for tooth-to-tooth shearing on one side of the mouth at a time. Excavations in the maxilla and dentary, for cheek pouches to retain the cut ends of plant material⁴⁷, had begun in *Fabrosaurus*. All known Triassic ornithischians had very long hind limbs with elongate distal extremities indicating very high speeds. A short trunk facilitates the maintenance of balance in a highly bipedal animal, but herbivory demands a long, bulky gut. Ornithischians solved the balance problem by rotating the pubis posteriorly so that the distal end, marking the end of the gut, lay far posterior to the acetabulum. Thus, the gut was extended between the hindlimbs and the pre-acetabular trunk section could be abbreviated⁴⁸.

Although Walker⁴⁹ has cited some resemblances between living birds and crocodile-like thecodontians (sphenosuchids), we believe that Ostrom has shown that the similarities between *Archaeopteryx* and small theropods are so detailed and comprehensive that the immediate ancestor of birds must have been a saurischian dinosaur^{1,8,50}. Some of the features cited by Walker as evidence of crocodile-bird relationships are actually widespread among tetrapods: cranial salt glands are developed in lizards, especially in *Amblyrhynchus*⁵¹; forearm articulations which force the radius distally during forearm flexion are present in salamanders, *Sphenodon*, and lizards. Although details are obscure, the *Archaeopteryx* skull seems much more like the light, kinetic skulls of small theropods than the solidly braced sphenosuchid structure⁵². *Archaeopteryx*

has the complete suite of seven features listed above as diagnostic of the primitive dinosaur erect gait. In flying birds, bats and pterosaurs the glenoid faces strongly outwards to make possible the abduction of the humerus necessary for gliding and powered flight. Significantly, *Archaeopteryx* retained the typical, downward-facing dinosaur glenoid; it is difficult to imagine how this joint would have made either flight or gliding possible. The initial evolution of feathers probably was not associated with flight, a hypothesis developed at length by Ostrom¹.

Ostrom has shown that the hands and feet of *Archaeopteryx* are identical in detail to certain Jurassic/Cretaceous theropods, and differ only in being larger relative to the body size (Fig. 3)^{1,50,53-55}. Feathers may have been widespread in bird-like theropods. *Archaeopteryx* strongly resembles small theropods in general body plan with a short trunk, thin, flexible neck, very long hindlimbs and long fingers bearing trenchant claws for snagging prey. Sphenosuchid thecodontians were quite different (Fig. 3) with a long trunk, thick neck and long forelimbs with short digits adapted for running and not prehension.

Fig. 3 Body form in a small theropod dinosaur, the first known bird and a crocodyloid thecodontian. *Microvenator* hand and skull restored after *Ornitholestes*. Data from refs 10, 53-55.

Endothermy and high aerobic exercise metabolism are sufficient justification for separating birds into a class distinct from other living sauropsid tetrapods. But endothermy and high exercise metabolism were probably already present in the dinosaur ancestors of birds and are the key features differentiating dinosaurs from crocodylians and the other extinct archosaurs. The bird radiation has produced many species, but the structural diversity is not more striking than that within the Ornithischia or Saurischia. Bird physiology is also rather stereotyped. The avian radiation is an aerial exploitation of basic dinosaur physiology and structure, much as the bat radiation is an aerial exploitation of basic, primitive mammal

physiology. Bats are not separated into an independent class merely because they fly. We believe that neither flight nor the species diversity of birds merits separation from dinosaurs on a class level. Among all amniotes, the most profound adaptive shift was from ectothermy to endothermy, which occurred during the origin of mammals and dinosaurs. Therefore we propose the erection of a Class Dinosauria, to include as subclasses the Saurischia, Aves and Ornithischia. The currently recognised suborders of dinosaurs would be elevated to orders (Fig. 4). Thecodontians, crocodylians, and pterosaurids

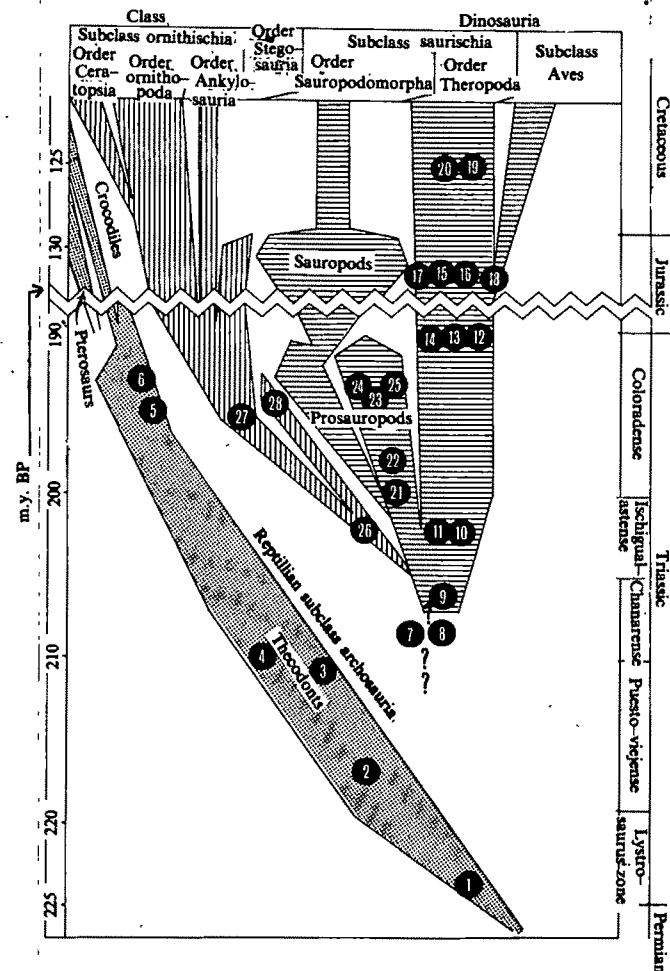

Fig. 4 Suggested phylogeny and classification of dinosaurs. Position of *Lagosuchus* and *Lagerpeton* is very uncertain. Within orders, ancestor-descendent relationship is not necessarily indicated by stratigraphic level of known specimens, for example, *Pisanosaurus* is earlier than, but in some ways more advanced than the earliest known *Fabrosaurus*. (1) *Proterosuchus*, (2) *Euparkeria*, (3) *Ticinosuchus*, (4) *Gracilisuchus*, (5) *Sphenosuchus*, (6) *Pseudhesperosuchus*, (7) *Lagerpeton*, (8) *Lagosuchus*, (9) *Staurikosaurus*, (10) *Ischisaurus*, (11) *Herrerasaurus*, (12) *Coelophysis*, (13) *Syntarsus*, (14) *Halticosaurus*, (15) *Coelurus*, (16) *Ornitholestes*, (17) *Compsognathus*, (18) *Archaeopteryx*, (19) *Microvenator*, (20) *Deinonychus*, (21) *Thecodontosaurus*, (22) *Efraasia*, (23) *Plateosaurus*, (24) *Ammosaurus*, (25) *Anchisaurus*, (26) *Pisanosaurus*, (27) *Fabrosaurus* and (28) *Heterodontosaurus*.

would remain in the reptilian subclass Archosauria, which would stand to Dinosauria much as the reptilian subclass Synapsida (the mammal-like reptiles) stands to Mammalia. This new classification, we believe, reflects more faithfully the major evolutionary steps. Ectotherms and forms transitional to endotherms are retained in the Reptilia and the two highly successful endothermic groups, mammals and dinosaurs, are given separate class status.

We thank J. Ostrom for data on *Archaeopteryx* and A. W. Crompton for access to fabrosaurid and heterodontosaurid material. Supported in part by the National Science Foundation.

Viroids and viral hepatitis in marmosets

DIENER¹ and Zuckerman² have recently speculated that hepatitis A and B, respectively, may be caused by infective naked nucleic acids or viroids. In response to their hypotheses, we felt it would be of interest to investigate the nature of an agent known to cause hepatitis in marmoset monkeys. We reasoned that if the aetiological agent of hepatitis found in serum is a free, or naked, nucleic acid in this system, then its infectivity should be destroyed by the action of a specific endonuclease. For example, a free viral DNA would be rendered uninfected after treatment with pancreatic DNase. The virus used in our study was the 'Barker' agent, originally recovered by Deinhardt *et al.* from acute phase sera of marmosets inoculated with serum from a human case of viral hepatitis³. This virus consistently induces hepatitis in such animals, although its pedigree as a human hepatitis agent has been a subject of controversy⁴.

As many animal sera contain RNase activity, but not DNase activity, we assumed the postulated viroid for Barker-induced marmoset hepatitis, if it existed, would most likely be a naked DNA. To test this assumption, we divided a pool of infective acute-phase marmoset serum into two equal aliquots. One aliquot was treated with pancreatic DNase (EC 3.1.4.5) at 20 µg ml⁻¹ for 1 h at 37° C; the other aliquot was heated to 37° C for 1 h without any other treatment. Three *S. nigricollis* marmosets were inoculated intravenously (i.v.) with treated serum (0.25 ml each); three other *S. nigricollis* marmosets were inoculated i.v. with untreated serum. The course of infection in each marmoset was monitored by measuring serum glutamic pyruvic transaminase (SGPT) and serum isocitric dehydrogenase (SICD) activities as indicator enzymes for liver damage.

All six marmosets demonstrated elevated SGPT and SICD activities by the fourth or fifth week after inoculation, indicating liver damages had been sustained in each animal. Clearly, then, the marmoset hepatitis agent cannot be a DNA viroid as all three animals receiving DNase treated serum showed convincing enzymatic evidence of viral hepatitis. The results of our preliminary study are consistent with the tentative finding by Deinhardt *et al.*⁵ that the Barker hepatitis agent bands in CsCl at a buoyant density of 1.2. Viruses usually band around $\rho = 1.2-1.4$, whereas free viral DNA bands at about $\rho = 1.7$.

While the possibility still exists that the marmoset hepatitis agent is another type of viroid, that is, a unique double-stranded RNA (or RNA:DNA hybrid)-protein conjugate which bands in CsCl at $\rho = 1.2$, our experimental evidence at least rules out the presence of a simple DNA viroid in serum containing the marmoset agent.

Nutrient transfer between the seagrass *Zostera marina* and its epiphytes

THE leaves of seagrasses often harbour dense populations of macroscopic and microscopic algal epiphytes. In many cases seagrasses grow in waters that are extremely low in dissolved inorganic nutrients yet they have high epiphyte standing stocks. These field observations led to direct experiments on the transfer of nitrogen and carbon from the dissolved nutrient pool in the interstitial waters of the sediments into the root system of eelgrass, *Zostera marina*, and through the plant to the algae on its leaves. Previous studies^{1,2} on seagrasses have shown that the high productivity of seagrass meadows is largely maintained by the nutrient pool of the sediments. Since the plant system leaks phosphorus and, presumably, other nutrients, it is possible that the production of the leaf epiphytes is indirectly sustained by the nutrients in the sediments. This mechanism has been suggested by several workers for marine and freshwater macrophytes³⁻⁷ but definitive experiments are lacking. Here we report the results of experiments designed to test this hypothesis.

Eelgrass, *Zostera marina* L., was collected from beds on Visovodof Island in the Aleutian Islands of Alaska, on August 6, 1972, a few hours before experiments began. Sediments were removed from the roots, and then plants were placed in partitioned plexiglass containers in which the water surrounding the leaves was isolated from that surrounding the roots and rhizomes (Fig. 1). Each experimental container held three plants with their natural epiphyte populations. Containers were filled with 3 l of filtered seawater in the upper level and 1.5 l in the lower. Since the plants grow in anoxic sediments, the lower water surrounding the roots and rhizomes was stripped of dissolved oxygen by bubbling with a helium-carbon dioxide gas mixture before the experiment. The seal round the plant between water levels was maintained by a septum stopper fitted to the lower stem and sealed by silicone stopcock grease.

We added $^{15}\text{N-NH}_4^+$, $^{15}\text{N-NO}_3^-$, or $^{15}\text{N-(NH}_2)_2\text{CO}$ to the lower compartment of each container in low (33 $\mu\text{gatom N l}^{-1}$) or high (67 $\mu\text{gatom N l}^{-1}$) concentration. In addition, 20 μCi of ^{14}C -labelled HCO_3^- was also added to the lower compartment of each container. The experimental containers were incubated for 8 h under natural light and ambient temperatures (about 12° C). The lower compartment of all containers was darkened.

At the end of incubation the plants were removed from a container, one was bisected into leaves and roots-rhizomes and frozen immediately, and the other two plants were dissected into leaves, stem, and roots-rhizomes and dried at 60° C for 24 h. The epiphyte community of a leaf was

FIG. 1 Partitioned container with *Zostera* for measuring uptake of carbon and nitrogen. Roots and rhizomes are in the lower blackened compartment separated at leaf base by septum stoppers; only the portion of the plant above the septum stopper is visible.

sampled by wiping the leaf on a glass slide and washing the algae removed on to a silver filter. After filtering, the epiphyte samples were dried at 60° C for 24 h and retained in a desiccator until analysed first for ^{14}C and then for ^{15}N content. The epiphytes comprised mainly several species of diatoms.

Carbon uptake by *Zostera* was measured by converting organic carbon to CO_2 by combustion and the radioactivity of the $^{14}\text{CO}_2$ determined in a liquid scintillation counter after the method suggested by Wetzel⁸ for aquatic plants. The ^{14}C content of the epiphytes was determined by Geiger-Mueller counting in a procedure similar to that for phytoplankton productivity⁹.

Nitrogen uptake was measured by determining the quantity of ^{15}N in the plant and epiphyte material. The organic

TABLE 1 Carbon and nitrogen uptake by roots of *Zostera marina* L. and transport through the plant to leaf epiphytes. Carbon values are single observations; nitrogen values are means of two observations.

	Roots and rhizomes	Stems	Leaves	Leaf epiphytes*	Roots and rhizomes	Stem	Leaves	Leaf epiphytes
Experiment I ^{15}N added as NH_4^+								
Low [N]	2.69	1.76	0.07	(0.03)	3.35	0.39	0.32	7.8
High [N]	11.83	0.27	0.13	(0.01)	4.16	1.01	0.25	7.2
Experiment II ^{15}N added as NO_3^-								
Low [N]	1.23	1.58	0.17	(0.01)	1.32	1.32	1.50	21.9
High [N]	5.91	0.24	0.08	(0.04)	1.82	1.33	1.88	6.5
Experiment III ^{15}N added as $(\text{NH}_2)_2\text{CO}$								
Low [N]	—NO DATA TAKEN—				0.025	0.033	0.051	8.7
High [N]					0.031	0.038	0.048	7.3

* Units for carbon uptake by epiphytes are μg per g leaf per hour.

Low [N] = 33 $\mu\text{gatom N l}^{-1}$.

High [N] = 67 $\mu\text{gatom N l}^{-1}$.

nitrogen was converted to N_2 by an automated Dumas technique¹⁰ and the ^{15}N content of the N_2 subsequently determined in a Bendix mass spectrometer. Uptake calculations followed the procedure of Dugdale and Goering¹¹. The data are presented as % uptake, and the relative velocity of nitrogen uptake; absolute uptake is obtained by multiplying the latter by the nitrogen content of the material.

The results of all experiments indicate a direct transfer of carbon and nitrogen from *Zostera* to the epiphytes on its leaves. ^{14}C labelled HCO_3^- and ^{15}N labelled NO_3^- , NH_4^+ , and $(NH_2)_2CO$ were all absorbed from solution by the root-rhizome system of the plant and the labels were subsequently transported to all parts of the plant and to the epiphytes on the leaves (Table 1). In all experiments after 8 h the ^{15}N content was larger in the epiphytes than in any part of the plant. Within a plant, a ^{15}N concentration gradient was observed with greatest amounts in the root-rhizome system and least in the leaves. The distribution of ^{14}C was generally similar to that of ^{15}N .

These results are positive evidence for the transfer of nitrogen from the sediments to the epiphyte community of a rooted macrophyte and could well be part of the explanation for how high standing stocks of epiphytic algae are maintained in waters with low concentrations of dissolved inorganic nutrients. It is possible that nitrogen and carbon are transferred directly from *Zostera* to the epiphytes as organic compounds, but transfer probably occurs by leakage of organic or inorganic compounds from the plant and subsequent uptake by the algae.

Previous experiments have shown that phosphorus absorbed by the root-rhizome system was in part lost across the leaves, so it is likely that this nutrient is also available for epiphyte growth. Harlin⁴ has shown that ^{14}C and ^{32}P -PO₄ could be transferred from *Zostera* to the algal epiphyte *Smithora naiadum*. In addition, Brylinsky³ has shown that several species of tropical seagrasses lose about 2% of the carbon fixed in photosynthesis across the leaves; the loss was in the form of low molecular weight organic compounds. The excretion of organic carbon and nitrogen has been measured in rooted freshwater macrophytes⁵⁻⁷.

It is likely that *Zostera* and most other seagrasses obtain their nutrients from the sediments through the roots. There is also evidence that some inorganic carbon is taken up by the roots and transported to a site where it can be fixed in photosynthesis. This mechanism has been found in some species of vascular plants in freshwaters¹².

Our work indicates a symbiotic relationship between seagrasses and their epiphyte community. This implies complexities in nutrient and productivity cycles in shallow waters dominated by rooted vascular macrophytes. Clearly, epiphyte productivity is enmeshed with that of its associated macrophyte.

This study was supported by a grant from the Oceanography Section, National Science Foundation.

Why kangaroos hop

KANGAROOS (family Macropodidae, order Marsupialia) are the only known group of large Australian herbivorous marsupials ever to have evolved major cursorial specialisations. During fast locomotion macropodids progress by a ricochet (bipedal saltation) involving a series of rebounds in which the two hind feet strike the ground at the same moment or practically synchronously and the forefeet not at all¹. In macropodids the axis of the hind foot is through digit IV which is unique among large cursorial mammals; perissodactyls and most rodents have the axis through digit III, while in artiodactyls, carnivores and leporids it lies between digit III and IV². These differences are the result of preadaptive complexes in the immediate ancestors of these groups.

The earliest placentals were probably terrestrial³ and the pes was primitively pentadactylous with a nonserial tarsus^{4,5}. Two basic vectors of weight transfer from the tibia to the digits were involved (Fig. 1A), one through the astragalus-navicular-cuneiforms-digits I-III, and the other through the astragalus-calcaneum-cuboid-digits IV-V. The non-serial tarsus made possible the option of a third vector of weight transfer which could pass through the astragalus to the cuboid and digits IV-V. The primitive tarsal configuration made possible a more or less equal distribution of weight transfer to each of the digits. Artiodactyls exploited the non-serial tarsus in development of a paraxonic foot with digits III-IV becoming the main supporting digits (Fig. 1B). In the development of a mesaxonic foot perissodactyls have reduced the astragalo-cuboid contact such that the tarsus is functionally serial⁶ (Fig. 1C). Cursorial specialisation in large placental herbivores are thus built upon the primitive placental foot structure. Placental carnivores have essentially retained the primitive tarsal arrangement with modifications being most evident in the reduction of lateral digits.

The first marsupials were probably arboreal⁶⁻⁸ and most likely had a hind foot structure similar to the living South American didelphid *Marmosa*⁹. The primary structure of the marsupial pes is adapted toward prehension, and its further specialisations reflect this derivation. Primitively the marsupial pes had a moderately large opposable hallux and digits II-V were of subequal size and length. The primitive marsupial tarsal arrangement has not yet been established although a non-serial tarsus seems most probable. The vector of weight transfer from the tibia to the digits was probably similar to that of primitive placentals.

Two major groups of pedis occur in Australian marsupials¹⁰. In the family Dasyuridae (marsupial carnivores) there is an elongation of the pes and parallel arrangement of the digits as well as recession of the hallux (Fig. 1D). The ancestral forms of this family seem to have abandoned prehensile modifications for semi-cursorial ones, the pes having been made servicable for rapid progression either in the trees or on the ground. Their terrestrial ancestors have substituted digitigrade for plantigrade progression⁹. Dasyurids typically have digits II-V of subequal size although there is a tendency for digits III-IV to be slightly larger. The vectors of weight transfer are thus similar to

those in placental carnivores. In addition, the primitive dasyurid pes has a pre-adaptive potential for evolution of major cursorial specialisations similar to those seen in placental ungulates; a potential which, however, has never been exploited.

FIG. 1 Mammalian pes (right). A, Hypothetical placental ancestor; B, artiodactyl; C, perissodactyl (*Equus*); D, dasyurid (*Dasyurus*); E, phalangerid (*Trichosurus*); F, peramelid (*Macrotis*); G, macropodid (*Macropus*). A, B, C, F and G after ref. 15. Abbreviations: as, astragalus; cal, calcaneum; cu, cuboid; ec, ectocuneiform; en, entocuneiform; mc, mesocuneiform; nav, navicular; digits I, II, III, IV, V.

The second line of Australian marsupial hind foot specialisation occurs in bandicoots (family Peramelidae), diprotodonts (family Phalangeridae and its derivatives) and in the common ancestor of these two groups. Digits II-III are reduced in size and bound together in the whole of their length by a skin sheath with the exception of their end joints and claws. This syndactylous condition is deemed to be a further arboreal adaptation^{7,8} and probably arose only once in the Australian marsupials⁹⁻¹⁵, although a diphyletic origin has been advocated^{16,17}.

In phalangerids (Fig. 1E), their immediate ancestors and the immediate ancestors of peramelids, digit IV is the major support digit of the hind foot, followed by digit V, then the hallux; digits II-III are very small and have ceased to play any part in walking, running or climbing and thus do not share in the more obvious functions that are associated with toes. The syndactylous digits have become a secondarily specialised toilet implement¹³. The major vector of weight transfer is through the astragalus-calcaneum-cuboid-digit IV, although part of the body weight is also carried through the astragalus-navicular-digits I-III vector. The common phalangerid-peramelid stock had a polyprotodont dentition¹¹.

Shortly after the acquisition of syndactyly, peramelids split off as a separate lineage from the syndactylous stock¹⁰. Peramelids retained a polyprotodont dentition⁹. Some peramelids progress by quadrupedal saltation (the spring) (for example, *Isopodon*) while others (for example, *Choeropus*) have become functionally monodactylous quadrupeds (Fig. 1F). In all peramelids digit IV is the main support digit of the hind foot, a character inherited from their arboreal, syndactylous, ancestors. Peramelids have deviated from the phalangerid tarsal configuration in rearrangement of the cuboid, ectocuneiform and metatarsal IV such that the ectocuneiform has been incorporated into partial support of metatarsal IV. The tarsal configuration in peramelids allows the greater part of the body weight of the animal to pass directly from the astragalus to the distal tarsals bypassing to a great extent the calcaneum¹⁵. As a consequence the syndactylous pes of peramelids is, in part, functionally convergent with ungulates. These particular tarsal modifications, found only in the Peramelidae, have allowed a small syndactylous marsupial to become a rather specialised cursorial quadruped. This tarsal configuration would, however, be impractical for body weight transmission in a large animal. Such changes in the peramelid tarsal configuration have

been influenced by the antecedent development of syndactyly¹⁸. Peramelids and macropodids represent two independent terrestrial adaptive radiations from arboreal ancestors; similarities in foot structure are thus the result of convergence⁹.

Macropodids evolved from phalangerids after the acquisition of a diprotodont dentition⁹. The potential for cursorial specialisations in macropodids was set by the preadaptive plasticity of the phalangerid foot structure for terrestrial locomotion. As digit IV was the major supporting digit in the phalangerid pes, cursorial specialisations would have to be built around this digit in macropodids (Fig. 1G). Evolution of weight transfer vectors in macropodids incorporating digit III was restricted by the presence of syndactyly of digits II-III in their phalangerid ancestors. This restriction excluded the possibility of evolution of efficient quadrupedal cursorial specialisations similar to those occurring in placental ungulates where digit III is partly (artiodactyls) or wholly (perissodactyls) incorporated as a major support digit. Utilisation of digits III-IV together in a support function could not have evolved in macropodids¹⁴. In ungulates a vector of weight transfer is incorporated which passes weight from the astragalus to the anterior tarsals and bypasses the calcaneum⁵. Macropodids have, however, exploited the vector through the astragalus-calcaneum-cuboid-digit IV and deviated from the phalangerid tarsal arrangement in the relationship between the astragalus, navicular, cuboid, and calcaneum; in macropodids the astragalo-calcaneum and cuboid-calcaneum contact are greatly enlarged while the astragalo-navicular contact is reduced. In macropodids there is no ectocuneiform-metatarsal IV contact. This is in contrast to peramelids. Incorporation of the calcaneum into the primary weight transfer vector is a common feature among ricochet mammals^{19,20}, while in digitigrade and unguligrade mammals there has been a progressive evolution to exclude this bone from the role of supporting body weight²¹. The macropodid tarsal structure allows effective ricochet function by transfer of weight through the calcaneum. The fact that their phalangerid ancestors had already developed syndactyly and the use of digit IV as their main support digit thus predetermined the type of cursorial specialisation possible in the macropodid hind limb.

These observations provide an explanation for Howell's statement²² that "In the case of the . . . kangaroo, it is doubtful whether it is sufficiently effective at locomotion to justify the evolutionary effort put into it . . . A kangaroo is an amazingly specialised animal, but its method of traveling by saltation was hardly begun for the purpose of ultimate speed. Rather has it built speed into the locomotory pattern that was already established, probably for some other purpose".

Banded mongoose males guard young

In most mammals care of the young is the prerogative of the female. The male, if present at all, contributes little. In the banded mongoose (*Mungos mungo*), however, males play an important role in guarding young at the den while the lactating females forage.

The banded mongoose is a diurnal social carnivore occurring in savanna habitats throughout much of Africa south of the Sahara. In Rwenzori National Park, Uganda, where I studied it for 2 yr, group (pack) size varied from approximately 5 to 40 animals. Reproduction within a pack was synchronised; several females typically came into oestrus at about the same time and subsequently produced their litters within a few days of each other. The young suckled indiscriminately from any lactating female and were groomed, played with, and transported by all pack members. They first began to leave the den for short afternoon foraging expeditions when 3 to 4 weeks old and at 5 weeks began to regularly accompany the adults in the morning. Until this age one or more pack members typically stayed at the den with the young when the others left for the morning's foraging. The pack usually returned after 2 to 4 h and for the remainder of the day the mongooses foraged intermittently in small groups. Occasionally however, a pack remained away from the den for an entire day.

To determine the sexes and identities of mongooses stay-

data for the 32 d in which marked animals stayed with the young. Twenty individuals were recorded guarding a total of 48 times. Adult males stayed with the young most frequently accounting for 73% of the total guarding records; 85% of the 20 mongooses which stayed alone with the young were adult males. The 9 marked lactating females were never recorded to stay with the young in the morning. Non-lactating females and animals less than 1 yr old occasionally guarded, but the latter did not remain alone with the young. Although the sample is small, it indicates that certain individuals show a greater tendency to stay with the young than others. In the E pack a male and non-lactating female accounted for 12 of the 17 guarding observations and two males accounted for 9 of the 11 observations in the F pack. Guarding was more equitably distributed in the I pack and 11 of the 17 pack members stayed with the young on at least one occasion.

The adaptive significance of guarding in the banded mongoose seems clear. Survival of young in the den is enhanced by the presence of an adult capable of protecting them from snakes and other ground predators while the lactating females are left free to forage. Future field studies of other species of social mongooses may reveal that male guarding of the young is characteristic of this group. My observations on *Suricata suricatta* indicate that one or more adults including males typically stay with young at the den and Rasa (personal communication) reports that this also occurs in captive *Helogale undulata*.

Male guarding in the social mongooses has few parallels in other mammals. Male marmosets of the genera *Saguinus*, *Cebuella*, and *Callithrix* are reported to transport the young from the time they are born transferring them to the female only for nursing¹. Among social carnivores, wild dogs (*Lycaon pictus*) usually leave a guard at the den with the young when the pack hunts and this role is shared in turn by females and particular males²; in most cases, however, it is the lactating female which guards although one or more males may accompany her³.

TABLE 1 Guarding of young in three banded mongoose packs

	Males	Adults		Unsexed	Juveniles and subadults (< 1 yr)	Total
		Lactating females	Non-lactating females			
Pack composition:						
E pack	8	4	2	1		15
F pack	13	3	13			29
I pack	8	3	3		3	17
Total	29	10	18	1	3	61
No. marked	21	9	13		3	46
No. marked individuals which guarded	13	0	5		2	20
No. times marked animals acted as guards	35	0	10		3	48
No. times marked animals guarded alone	17	0	3		0	20

ing with the young in the morning three packs were live-trapped and individuals ear clipped and marked in distinctive patterns with Nyanzol fur dye. All mongooses in one pack were marked but it was not possible to trap all members of the other two packs. Mongoose packs ordinarily change dens every few days. When the den site of a marked breeding pack was known, I observed and recorded the total number of mongooses leaving each morning and the identities of those marked. Any marked animals staying in the den could then be determined by the process of elimination. On some occasions a guard emerged with the pack and then returned to the young when the others left. Usually only one mongoose stayed at the den (77% of 57 observations) but up to 6 guards were recorded. On three occasions all pack members went off leaving the young alone.

Table 1 gives the pack compositions and the guarding

book reviews

Piaget on memory

Memory and Intelligence. By Jean Piaget and Bärbel Inhelder, in collaboration with Hermine Sinclair-de Zwart. Pp. xii+414. (Routledge and Kegan Paul: London, September 1973.) £5.25.

WITH the appearance of an English translation of this book there is now available to the English speaking world a full circle of Genevan writings that focus on particular topics of cognitive functioning.

In the introductory section of the book Piaget and his co-authors link up the words "memory" and "conservation". Memory is seen as an organism's capacity to conserve something over time; but is all conservation identical with what is called memory? Conservation could include here the entire genetic past inherited by an individual, as well as the modifications he acquires during his lifetime, many of which are conserved more or less indefinitely. Piaget is willing to speak of "memory in the biologist's sense" with an extremely broad meaning for memory which includes both physiological (acquired somatic responses) and behavioural modifications.

"Memory in the wide sense" includes conservation of behavioural habits together with recall of memory images and acts of recognition. Here, however, Piaget follows the logic of his own structural theory and makes two crucial points. First, recognition, if it means the recognition of perceptual signals, is an integral part of all perceptual or behavioural habits and must be clearly differentiated from a higher-level capacity to conserve and recall an image. Second, if conservation of habits (such as eye-hand coordination or spatial know-how) is ascribed to memory, then all further action-knowledge (and for Piaget knowledge at all levels is primarily action or 'operative' knowledge) must also be included in this memory. But an operative scheme, whether on a practical (sensori-motor) or theoretical (operator) level, is not something a person remembers but something he has or is. Thus a person with the operative scheme of, say, classification does not have to remember class inclusion but simply knows that—given that London is in England—there are more people in England than in London. This kind of knowledge (or understanding) is conceptualised as being based on a hierarchy of operative schemes (Piaget calls it "schematism"). These schemes are general instruments

of assimilation of incoming data and at the same time they are accommodated when applied to particular data.

Consequently the conservation of general assimilatory schemes that are integral and permanent belongings of the person must be distinguished from the conservation of particular accommodations that took place at a certain time during the person's past. The first kind of conservation is based on internal self-regulatory mechanisms that assure the scheme's permanent functioning, whereas only the second kind of conservation can be called "memory in the strict sense". Piaget's aim in this book is to investigate the relation between the first and second kind of conservation. This aim is implied in the book's title: *Memory and Intelligence*, where memory is taken in the strict sense and intelligence means the totality of schemes available to the child. These schemes develop in the course of the child's life experiences and the resulting changes from sensori-motor to pre-operator and finally to operator stages are reflected not merely in the child's operative structure of intelligence but also in his memory. For it is hypothesised that this operative structure is essential in the structuring and restructuring of input to be retained in memory.

Parallel with the distinction just outlined goes the contrast between the operative aspect of knowing which emphasises the actively transforming and assimilating character of knowledge and the figurative aspect which emphasises the accommodation pole of knowledge, namely the relatively static character of a particular sensory configuration inherent in any concrete object or event. A related distinction—important to a discussion of memory—is between the signifying and signified (or meaning) aspect of a sign. The various distinctions can be related to this topic by stating that memory in the strict sense emphasises the figurative aspect of knowing, that recognition is basically an undifferentiated sensori-motor signal reaction, while the memory response of reconstruction and recall is a differentiated signifying symbol. A memory image is sometimes called a schema—a simplified figurative model that serves as a mnemonic device—and must not be confused with the operative scheme on which the meaning aspect of a mental image is based. None of the above distinctions must be taken in an absolute or isolated sense: they are interrelated

aspects of a person's cognitive functioning.

Within this developmental and epistemological framework Piaget and his co-authors describe their programmatic research on memory. Twenty chapters cover investigations dealing with memory for additive logical structures, multiplicative logical structures, causal structures and spatial structures. For example, there is the report in chapter 4 on the remembrance of conflicting numerical and spatial correspondences. This conflict is brought about by the display of a straight line of four matches and below it, aligned from the left, another W-shaped line of four matches. Therefore, the child saw two lines which had the same number of identical sticks but differed in left-to-right extension. After a week and again after 6 months children were required to make a memory drawing. The responses of the children were classified into five types: 1, elimination of one line; 2, two lines of equal length, one straight, the other zig-zag, of undetermined number; 3, two lines of four matches with an attempt to equalise the boundaries; 4, two lines of an arbitrary number with the straight line correctly projecting; 5, correct in number of matches and length. Types 2 to 4 indicate different ways of solving the conflict between 'same number' and 'different length'. The children's memory solutions were clearly related to developmental age; types 2 to 4 were observed in many of the younger children after a week, but only in children from 7 years on after 6 months. The authors conclude that memory after 6 months, even more than more recent recall, is subordinate to the availability of operative schemes which in the present case meant co-ordination of apparently conflicting numerical (same) and spatial (different) correspondences.

English-speaking psychologists will probably find many places where the reporting is too global and qualitative or where the table of results or the criteria for scoring are not unequivocally defined. But these investigations can and should be critically scrutinised, evaluated, replicated and modified by the scientific community. Certainly lack of methodological finesse need not blind the reader to the substantive questions on memory with which these investigations are concerned. Although Piaget's style is far from being an example of clarity, it has an internal consistency which allows the motivated reader to recognise the un-

derlying thinking. But when a professional translator, apparently without an adequate understanding of Piaget's theory, goes to work and renders the author's cumbersome French into well formed English sentences, the result, as seen in this book, can be truly disastrous. The very first pages are so full of translation errors that comprehension of Piaget's position on the basis of this introduction is out of the question.

For example, the translator does not stick to the same words in translating the original words: memory, remembrance, recognition, recall, which are definitely not interchangeable. 'Imprinting' is a technical term used by the translator where 'registration' would have been more appropriate. The French 'ou' can mean an equivalence (remembrance = conservation) or a disjunctive alternative (remembrance of schemes or of data): the translation does not clarify this ambiguity. In page 3 paragraph 3, "Habit . . . concerns that part of the memory we call recognition", is the translation given for Piaget's "habitat . . . includes recognitory memory". Where Piaget carefully distinguishes operational (in contrast to pre-operational) and operative (in contrast to figurative) the translation generally renders both words as operational; similarly, Piaget's distinction between an operative scheme and a figurative schema is largely confused.

After the introduction the reporting of the investigation is less theoretical and the translation is no longer replete with serious and confusing errors. Piaget's writings are certainly a problem, admitted by him and all, quite apart from translation. I hate to think of anything like an 'official' translation, yet this translation is not only inadequate but totally confusing as regards a potential comprehension of Piaget's psychological theory. With this proviso I recommend to all persons interested in Piaget's theory this important addition to his work on cognitive functioning and its development.

H. FURTH

Filling a nuclear gap

The Fundamental Particles. By B. H. Bransen, D. Evans and J. V. Major. Pp. vii+284. (Van Nostrand Reinhold: London and New York, September 1973.) £10.50.

THE continuing expansion of nuclear physics research and the increasing adoption of short unit lecture courses in physics departments has led to the splitting of topics within nuclear physics. This is undoubtedly good practice and the physics of fundamental particles is an obvious unit choice. This book, aimed at the undergraduate student, is well written and presented and should

serve its purpose as an introductory text. It contains a series of useful problems at the end of each chapter and is supplemented by some mathematical appendices on such topics as angular momentum, transition rates and the Weyl and Dirac equations.

After an introductory chapter, the authors concentrate for two chapters on the experimental methods of accelerating, transporting and detecting particles and measuring their masses and lifetimes. The treatment is selective but detailed. Then follow chapters on the conservation laws, symmetry principles and intrinsic quantum numbers. The pion-nucleon interaction is treated in detail using partial wave analysis. This chapter is very well put together. A chapter on mesons is followed by a discussion on the classification of particles including the quark model and the Regge classification. A description of high energy collisions follows. The authors conclude their book with chapters on electromagnetic properties and weak interactions.

The coverage is thus very extensive but the interest of the reader is well maintained throughout. The mathematics assumes some acquaintance with quantum mechanics. I find the book exceedingly readable. The introduction to each chapter is commendable. There is almost a complete absence of references in the text but a brief bibliography leads the reader onward.

This book adequately fills a gap between the simple and more advanced treatises on the subject, though its price is high.

P. R. BLAKE.

Astronomy updated

Astrophysical Quantities. By C. W. Allen. Third Edition. Pp. x+310. (Athlone), University of London. London. Distributed by Tiptree, Essex, November 1973.) £6.25.

THE eagerly awaited third edition of Professor Allen's invaluable reference book proves to be slightly disappointing. As far as updating the previous edition is concerned, Allen has done a good job, but the sections devoted to topics which have grown up since the early 1960s are less satisfactory. The "entirely new sections" include plasmas, solar wind, solar XUV, pulsars, cosmic X-rays, quasars and Seyfert galaxies. But the pulsars section consists merely of half a page defining the variables relevant to the study of these objects and a table giving the parameters of only thirteen pulsars; even three years ago a much more useful compilation of pulsar data were provided by Maran and Modali (*Earth and Extraterrestrial Sciences*, 1, 147; 1970), a source to which Allen does not even refer. It is a similar tale with

the other new sections.

The virtue of previous editions has been that they covered just about everything, removing the need to hoard articles such as that of Maran and Modali. But it is a remarkable achievement for one man to have produced the original version of *Astrophysical Quantities*, let alone ensured that the latest edition is still invaluable almost 20 years after the original appeared.

In his preface, Professor Allen suggests that the time to begin work on the fourth edition is now and asks for offers of help with its presentation. I hope that some dedicated practitioner of the new astronomy will indeed be willing to collaborate with Professor Allen on the daunting task ahead.

JOHN GRIBBIN

How behaviour develops

Behavioral Embryology. Edited by G. Gottlieb. Pp. xix+369. (Studies in the Development of Behavior and the Nervous System 1.) (Academic: New York and London, October 1973.) \$22.50.

THE first of the four sections in this book is an introduction to behavioural embryology, by G. Gottlieb. Then there are sections on embryonic motility and its neural correlates (Hamburger; Provine; Foelix and Oppenheim; Berrill); hatching: hormonal physiological and behavioural aspects (Oppenheim; Corner, Bakhuis and van Wingerden); and sensory processes: embryonic behaviour in birds (Vince; Impeken and Gold).

The subject is obviously of the first importance; few would quarrel with the idea that one of the best ways of approaching an understanding of adult form and function is to study their development. It is a pity that the misleading name 'behavioral embryology' has been adopted for what should be the embryology (or ontogeny) of behaviour.

The first two volumes of this series are intended to present a "detailed explication of the major 'philosophical', theoretical and empirical issues" involved. Since Gottlieb's introductory essay is presumably partly an attempt to explicate the philosophical, theoretical and empirical issues, it is somewhat disconcerting for the reader to come across an apparent confusion (pages 31, 32) between neural specificities and neural connections, which are not at all the same thing. Dr Gottlieb is in good company here, since this is a fairly widespread confusion. It does suggest, however, a certain laxity of approach; and this impression is not helped by a passing reference (page 25) to retinal cells connecting ("in a general way") to cells in the visual cortex.

An almost mystical element is introduced in some of the arguments in Hamburger's paper on the anatomical and physiological basis of embryonic motility in birds and mammals. Hamburger draws attention to the incongruity between neurogenesis and overt motility in amniote embryos. The unorganised movements of the 4-17-d-old chick do not, apparently, reflect the neurogenetic events going on, so to speak, below the surface. From these observations Hamburger claims that it is not valid to generalise that neurogenesis fully explains behaviour. And he makes the remarkable statement that "even the most detailed knowledge of neural organisation, including all significant synapses, in chick or rat embryos at a given stage would permit no prediction of the actual (type 1) movements performed at this stage". This viewpoint must command respect; but it surely does so as a statement of faith, of scientific position, rather than as a rigorous argument from observed data. It cannot be the latter, of course, since too many of the premises are hidden: as Hamburger points out, the observations on movement are crude and the information available on structure and ultrastructure is deplorably inadequate. After further arguments involving the results of transplanting parts of the embryonic spinal cord, Hamburger comes to the conclusion, with which I agree, that the conceptual dichotomy of coordinated against uncoordinated movements is perhaps too rigid and that such dichotomous thinking should give way to a more flexible scheme.

This book is interesting and contains much relevant information. Even arguments with which individual readers may disagree are worthwhile if they stimulate thought on this subject, where thought is badly needed.

R. M. GAZE

Computed structures

Molecular Structures and Dimensions, Vol. A1: Interatomic Distances 1960-65; Organic and Organometallic Crystal Structures. Edited by Olga Kennard, D. G. Watson, F. H. Allen, N. W. Isaacs, W. D. S. Motherwell R. C. Pettersen, and W. G. Town. (N.V.A. Oosthoek's Uitgevers Mij: Utrecht; distributed by Crystallographic Data Centre, Cambridge and Polycrystal Book Service, Pittsburgh, 1972.) n.p.

To discover the structures of molecules has been one of the main aims of chemistry since the science began. To discover the dimensions of these molecules only became possible with the advent of X-ray crystallography and various spectroscopic methods. By 1960 a very

large amount of information had been accumulated on interatomic distances and the configurations of molecules and ions. L. E. Sutton was a pioneer in the compilation of all this data, a task continued by the Chemical Society in its Special Publications.

About 1960, however, a profound change began to take place in the methods of X-ray crystallography. Fast computers and automatic diffractometers became available. The collection and analysis of X-ray measurements were vastly speeded up, and the accuracy of structure determinations greatly increased. About this time it began to be realised that the structure of an unknown molecule like a natural product could be determined more quickly and with greater certainty by the methods of X-ray crystallography than by the classical methods of organic chemistry. All this has led to a spectacular increase in the number of structure determinations from the early 1960s onwards. Up to 1972 about 8,500 organic and organometallic structures had been published, and each structure usually contains a very large amount of accurate numerical data. This output is now far beyond the capacity of the ordinary textbook to handle. But the computers that created the problem have now come to the rescue.

The Crystallographic Data Centre in Cambridge, with the sponsorship of the Office for Scientific and Technical Information have a computerised data file which contains all this information and to which about 1,500 new entries are added annually. Annual bibliographic volumes are published. The present volume is the first to give all the numerical data for organic and organometallic structures, and covers the years 1960-65. Although it modestly claims to present interatomic distances, as a continuation of Sutton's work, it does in fact cover much more than this. In addition to the chemical structural formula each structure is illustrated by a beautifully drawn stereoscopic pair (viewer provided) which has been computer generated from the published atomic coordinates. The numerical data give bond lengths, bond angles and torsion angles. These are all recomputed from the published coordinates and discrepancies noted. The torsion angles, which provide vital information concerning molecular conformation, were seldom given in papers published between 1960 and 1965 and so this volume contains a vast mine of new information. Another valuable feature is the inclusion of the *R*-factor for each structure, giving an indication of its reliability. It is interesting to note that for the 791 full three-dimensional structures listed, the *R* values range from 0.02 to 0.29, with a mean

value of about 0.10. A value of about 0.06 indicates a very accurate analysis, while a value greater than about 0.15 indicates the need for further refinement in most cases, unless the structure is extremely complex with some disorder.

The layout of the whole volume is excellent, but unfortunately it is not easy to read all the atom numbers on a few of the more complex diagrams, such as for vitamin B₁₂ and epilimonol iodoacetate. Those whose eyes do not adapt easily to stereo vision might have preferred a single larger diagram. But on the whole this is a magnificent production and Olga Kennard and her co-editors must be congratulated on their achievement. I hope and trust this heroic task will be continued with the future volumes that are contemplated. All scientists interested in molecular structure are greatly in their debt.

J. MONTEATH ROBERTSON

How to be a petrologist

Experimental Petrology: Basic Principles and Techniques. By Alan Edgar. Pp. xi + 217. (Clarendon: Oxford; Oxford University: London, October 1973) £5.75.

Books written for research workers are, in overwhelming majority, about what to think and do; they represent an attempt on behalf of the author to fashion the way his readers will approach their research problems. In contrast, this book sets out to describe how to do something: in this case, experimental petrology. It is unashamedly a recipe book destined to be fingerprinted with molykote and bleached with spots of dilute nitric acid.

In fulfilling this aim, the author has described clearly and accurately the anatomy and function of the sort of apparatus a new researcher might expect to find in any established laboratory of experimental petrology. This book will answer in advance many of the questions such a person would need to ask during their first months in the field. But the aims seem to go deeper than this as there is a quantity of detailed information about the essentially engineering side of the subject which would only be of concern to a person setting up a laboratory from scratch. I doubt whether it is realistic to hope that any book could include enough of this sort of detail to be fool-proof but at least the present work gives a reasonable guide to the literature and compares different techniques (for example starting materials) in a sensible and unbiased manner.

The level of theoretical background given is uneven. Buffers for controlling

the chemical potential of volatile species are dealt with in some detail (although I was surprised to find no reference to the work either of Burnham, Holloway and Davis or of Presnall on the PVT of water and hydrogen respectively). On the other hand, the treatment of one, two, and three component systems in chapter 2 is very cryptic; for example, the free energy of binary solutions receives less than one page and will surely convince most non-initiate readers that there is a large element of magic in thermodynamics.

But this book's great merit is that it does what it sets out to do and at £5.75 represents a worthwhile investment to anyone about to embark on research in the field of experimental petrology.

S. W. RICHARDSON

Life on Moon and Mars

Origins of Life: Planetary Astronomy. Edited by Lynn Margulis. (Proceedings of the 3rd Interdisciplinary Communications Program Conference.) Pp. xi+268. (Springer-Verlag: Berlin and New York, 1973.) DM46.70; \$16.50.

THIS is a verbatim report of the third of four conferences on the origins of life. The style of the volume follows that of its predecessors (see *Nature*, 235, 404; 1972; and 239, 175; 1972). The publisher, however, has changed, and the price has come down by over 40%. The conference, too, was organised differently. On this occasion the purpose was to explore the effect of space exploration on ideas about the origins of life. For the purpose, eight planetary astronomers, who were personally involved in space programmes then current, were assembled to meet ten practitioners interested in the origins of life (three exobiologists, two microbiologists, four chemical prebiologists and one palaeontologist). A fair proportion of the biologists had attended at least one of the previous conferences, but most of the astronomers were there for the first time. The conference was held in February 1970.

There was not the same 'free for all' that characterised the earlier conferences. On the contrary, there was a rigid division into two halves, the first devoted to the Moon, the second to Mars. In each division, certain of the astronomers were asked to discourse on aspects of their topic that they thought might interest the biologists. The biologists were encouraged to interrupt, and to ask questions. During the first division, Shoemaker, Wasserman, Kaplan and Singer discoursed on the Moon; then Oró went into considerable detail on the chemical search for carbon compounds in lunar material, and Young went into the methods

adopted in the search for microbiological activity. In the second half, Murray, Owen and Leovy spoke about Mars. Some biological interest was aroused in the part that nitrogen might or might not play in life on the planet.

But the book, if not the conference, seems to have failed in its objectives. The timing was unfortunate. Knowledge of Mars has changed dramatically with the new data collected by Mariner 9 in the following year, and the review of the Moon (which, in any case, is of less biological interest than Mars) was based on data emanating from nothing later than Apollo 11. There has been a three-year delay in publication, and the field is just moving too fast for such a leisurely programme. The conference lacked the enthusiasm of its predecessors. The book is not only out of date; it is dull. Better accounts of both the astronomy and geology can be found elsewhere. It is especially to be regretted that no attempt was made to reproduce the illustrations of lunar and Martian topography which, from all accounts, formed a major feature of the conference.

P. C. SYLVESTER-BRADLEY

Well digested Protozoa

The Biology of Protozoa. By M. Sleight. Pp. viii+315 (Arnold: London, October 1973.) £7.50 boards; £3.75 paper.

RECENT spectacular increases in knowledge of the genetics, biochemistry and ultrastructure of the Protozoa have greatly increased the difficulty of writing a satisfactory book of modest size on this group. Dr Sleight has attempted to produce in 300 pages, at about degree level, a general biology of the Protozoa, for the most part successfully.

After a brief introduction on evolutionary relationships and cellularity, three chapters are concerned with structure, metabolism and reproduction. Of the remaining seven chapters, six are devoted to taxonomic groups. It seems to me regrettable that the general treatment with which the book begins (and ends: chapter 11, "Ecology of Protozoa") was not carried through completely. But repetition, which is liable to occur in combining a systematic with a subject approach, is largely avoided by numerous cross references. Complex ascriptions in the text are minimised by the numerical reference system; hence the presentation is one of digested rather than of quoted information. Occasionally one could wish for more references to the sources of information, as in Table 5.1 of "Features of Various Flagellate Groups".

The illustrations are of diverse kinds, light and electron micrographs, draw-

ings and diagrams and are generally fresh and apposite although some of the drawings of whole animals made them look, to me, more solid and opaque than protozoa usually do in the microscope.

This is altogether a valuable and timely book of the right size for use in undergraduate courses.

G. CHAPMAN

Mediterranean collection

The Mediterranean Sea: A Natural Sedimentation Laboratory. By D. J. Stanley. Pp. xvi+765. (Dowden, Hutchinson and Ross: Pennsylvania; Wiley: Chichester, September 1973.) £22.50.

THIS volume is a collection of forty-seven papers brought together out of the feeling that the Mediterranean Sea is an ideal environment for the study of marine sedimentation, and in the belief that sedimentological work in this area, cutting across linguistic and national boundaries, should be summarised in order to speed future investigations. The papers are divided between twelve sections touching on many different aspects of the Mediterranean, its bathymetry and hydrography, the geological setting up to and including the Quaternary, clastic and non-clastic sedimentation on shelves and in coastal areas, deep-water sedimentation, and geochemistry. There is a paper on pollution of the Mediterranean and another sketching which topics should be given priority in research in the next decade.

Although a commendably high editorial standard is apparent, the content and relevance of the papers are uneven and not wholly representative of recent work in the Mediterranean. Some papers are regional or subregional in scope, whereas many deal with what could be purely local problems, and a few simply use the Mediterranean as the setting for the study of a general topic. Among these personal original endeavours, I sorely missed attempts at regional syntheses specific to the Mediterranean, which would aim to show in detail what was known and what remained to be studied. It is easy from this book to discover fairly completely who is doing what and how—it is excellent as a compilation transcending national differences in scientific outlook—but I am less confident that a critical light has been focussed on the major research problems of the Mediterranean and its hinterlands. A different blend of original papers and critical reviews might perhaps have led to a book greater than the sum of its parts.

J. R. L. ALLEN

matters arising

Evolution of the Tasman Sea

SIR,—Hayes and Ringis¹ have presented an interesting model for the evolution of the Tasman Sea. I wish to call attention, however, to what I feel is an inappropriate reference to an earlier article by myself and Brennan². Hayes and Ringis¹ state that: "A cursory examination of widely spaced east-west aeromagnetic profiles between Australia and the Lord Howe Rise led to the early but incorrect conclusion that there were no lineated magnetic anomalies within the Tasman Sea." But in discussing the possibility of lineated anomalies in Tasman Sea we stated that: "While the lack of correlated north-south anomalies cannot be proved conclusively from our data, if such correlation does exist it is not apparent."

Furthermore we said: "But the fact that the individually widely spaced magnetic profiles resemble magnetic profiles produced by the process of seafloor spreading means that the possibility that these magnetic anomalies were produced by an earlier episode of seafloor spreading cannot be excluded. This earlier period of seafloor spreading could have been complex, requiring a closely spaced survey to detect its presence." From our study we concluded that: "A more detailed survey should be conducted to resolve these two contradictory ideas (that is, lineated as compared with nonlineated anomalies) concerning the source of the anomalous magnetic pattern formed in the Tasman Sea."

Unfortunately, some confusion may result from the title given to our letter

on the index page of the issue in which it appeared. It was referred to as: "No seafloor spreading in the Tasman Sea," perhaps an unfortunate summary in view of the above.

My present comment does not, of course, effect the substance of the Hayes and Ringis paper but merely seeks to clarify the interpretation of an earlier reference.

Yours faithfully,
PATRICK T. TAYLOR

science on television

Under the BBC's bushel

John Gribbin and Fiona Selkirk

IF you ask the average scientist in the street (let alone the apocryphal man on the Clapham omnibus) what science programmes are to be found on British television he would probably reply "Well, there's 'Horizon', of course, and the Open University, and I think there was a programme about anorexia on ITV the other day, and sometimes odd bits late at night on BBC." In fact, those odd bits amount to regular broadcasts in 30 weeks of the year (excluding repeats) under the guise of further education. But the BBC in general, and *Radio Times* in particular, is so coy about this output that it is difficult to find what is on, and when, at the best of times. Recently, these programmes have suffered because of restrictions on late night television (in Britain that means after 2230) and because of the subsequent domination of our screens by election programmes; so these difficulties have been greatly enhanced. We therefore found it necessary to resort to a visit to the BBC Tele-

vision Centre, where several hours spent in a viewing room provided the material needed to comment on this almost undercover output from the BBC.

Of the forthcoming attractions "The Experimenters", provisionally scheduled to be shown on BBC1 on Mondays from April 22, will probably be of considerable interest to a scientifically knowledgeable viewer.

It is seldom possible to combine scientific research with vocational work and the choice after graduation is a difficult one to make and even more difficult to go back on if the choice transpires to have been wrong. A doctor in a mining community in South Wales has, however, managed to do just this and plans to provide some useful information about the occurrence and development of gut cancer, while still practising medicine in the community. He is the 'experimenter' in one of these programmes. The series attempts, and if this example is representative, succeeds, in looking at the people behind scientific research, their methods and motives.

This doctor tried pure research and decided he wanted to know his 'guinea pigs' as people. He took up general

practice and is starting a survey into gut cancer using his patients as the subjects.

The scene of his meeting with the local community in one of the local clubs—on Bingo night—is effective. The attentive, slightly worried faces of his audience are intriguing as he explains what he is trying to do. "Why is this survey being done here and not in London?" he was asked. With a wry smile, he explained about population stability and community spirit, features not exactly characteristic of the population of an average big city.

There are problems involved with doing this kind of research, the biggest being communication, but this doctor argued convincingly that the feedback from research improves his value as a general practitioner even if the research turns out not to be of any great significance in itself.

Even in the laboratory, however, the halcyon days of scientific breakthroughs being made by a lone researcher are gone and today scientists have to work in teams. The choice of team mates is critical or research can grind to a halt through personality differences, even though the minds behind those per-

sonalities may have the same goal.

This concept was well illustrated by the differing attitudes to the controversial results of some research by a team of three more 'experimenters' in the series.

Drs Walter Kellerman, Gordon Brooke and John Baruch are now famous as the team that might have discovered a quark, or not, as the case may be. Baruch is brashly convinced of the validity of their cosmic-ray experiments, and hustled his colleagues into publication. "Why let someone else get the credit?", he argued. Brooke seemingly regrets this haste and says that he would not have published this claim without more evidence, if he had had his way. And Kellerman, balancing these extreme views and presumably with the casting vote, decided in favour of some publicity, to encourage further work in the field (and, no doubt, to encourage further grants to the group at the University of Leeds).

The discussions between the members of the team certainly showed the human face of science (with a few small warts); and Kellerman was heretical enough to point out that the 'scientific method' is a mythical beast.

Two other programmes came from series already screened and perhaps even seen by those people who were able to find out that they were on. A look at some of the 20,000 or so tiny creatures that share the average house with its

human occupants was not for the squeamish adult but, overall, with light-hearted narration, a remarkable range of background music and some expert photographic work, it was just the stuff to give an appreciative audience rather earlier than 2325—although perhaps not just after supper.

The combination of some of the best photographic techniques (the use of light and scanning electron microscopy, time-lapse and excellent closeup camera work) makes this extremely successful visually, rivalling the best of "Horizon", "The World About Us" and others.

As for "Bellamy on Botany", Dr David Bellamy has, through the force of his own personality, ensured that his contributions to the further education output are reaching a wide audience. Bellamy has the character and personality to carry a programme transmitted live from a sewer (perhaps this will come in due course), but the programme we saw came from the clean dunes of Holland; we learned how natural reclamation of land from the sea takes place as plants establish stable dune formations.

The comparison with programmes such as "Horizon" is again favourable—especially so since, as we were told, a number of further education programmes can be produced for the cost of one "Horizon". These programmes may be labelled education, and that may put off some casual viewers, but as we saw they can be as hard hitting as any cur-

rent affairs programme, or as entertaining as any feature, as well as being educational.

And what of programmes aimed specifically at schools? One silver lining to the recent rail travel troubles in southern England has been the opportunity to view some of these, along with several thousand schoolchildren and an unknown number of housewives. On the basis of this limited opportunity, the scientific programmes for schools, especially those for 16 to 18-year-olds, are every bit as good as their late night counterparts. Indeed, many of them could be shown unchanged in the evenings, and it is rather odd that although further education programmes are sometimes repeated for schools, the reverse flow is non-existent. Here, surely, is a useful way to occupy the 22 weeks when further education programmes disappear from their usual slot.

But one thing is certainly clear. There is no need to worry about the health of science on television in Britain; it is alive and well, and living under the name of "further education". What is worrying is that these programmes receive little or no promotion, and that those responsible for screening and publicising the programmes seemingly lack the imagination of the people who produce them. Until this situation is improved, a little research into the small print of the *Radio Times* is likely to prove a very rewarding exercise.

Announcements

Erratum

In the article 'Lyoluminescent tissue equivalent radiation dosimeter' by Nadir A. Atari and Kamil V. Ettinger (*Nature*, 247, 193, 1974) there is a misprint in the title: 'dosimeter' appeared as 'desimeter'. Also paragraph 6, line 10 should read ... 'between 1 and 10⁶ rad ...' not ... 'between 1 and 60⁶ rad ...'.

Outlook with Labour

MR WILSON has eventually secured what most expected him to, and the political outlook, precarious as it is, is unlikely to force him into another election before he has had time to govern for six months to a year.

It was apparent immediately Mr Wilson announced his Cabinet that this was not to be a palliative government, shaped to defuse the Liberals and other parties. Three key posts, Employment, Industry and Trade go to three left-wingers Messrs Foot, Benn and Shore—vigorous proponents of nationalisation and renegotiation of the European Treaty. Unlikely as it is that moves towards nationalisation will come in the next few months, it is almost certain that within a year this Labour Government would be moving towards public ownership in several industries.

The three appointments that will most interest British scientists are those of Mr Roy Mason to Defence, Mr Eric Varley to Energy and Mr Reg Prentice to Education and Science.

Defence isn't what it used to be. The great debates on Britain's nuclear deterrent and her world posture are now part of history and there is a deep lack of interest in defence problems. The only highly visible role of the armed forces is in Northern Ireland, the last and most insoluble of the colonial peace-keeping problems. This is an operation that many tough-minded citizens would like to see terminated 'to let the Irish sort it out for themselves', and certainly few outside military circles give military matters much thought.

This is a bad situation. The military mind left to its own devices will expand outrageously. Mr Mason is committed by the Labour Party's manifesto to prune hundreds of millions of pounds off defence spending and will meet fierce resistance. In the past two years military research and development expenditure, having declined steadily for years as a fraction of total military expenditure, suddenly started to rise again. Much is in the pipeline, such as the Multi-Role Combat Aircraft and improvements to the Polaris fleet. Mr Mason will, no doubt, squash plans for the refitting of Polaris. He might well start enquiries into the long term future of anti-submarine warfare and nuclear weapons development.

Mr Varley comes into a young ministry and has many well-wishers. Not, as one newspaper put it, because "his mining experience should be useful" as if years of handling coal gave one a special insight into energy problems shared only by petrol-pump attendants. Rather, his is a relatively unknown face and there is hope that a fresh mind, not too blunted by previous political battles, could do a good job in this demanding ministry.

The first major issue that he will have to consider is the nuclear reactor question. This is one of those de-

cisions in politics which despite all the finely calculated analyses and extensive documentation will be made on instinct. Noises before the election suggested that the instincts are rather strongly against light water reactors, and in favour of the very cautious step of more magnox reactors.

Mr Prentice is rather a surprise at Education and Science. He had been at the ministry before at a junior level, but has recently been 'shadowing' employment. However, his well-known dislike of the left-wing made that an impossible post for him. Education and Science may still only be a temporary staging post.

It is most unlikely that science will see any major changes in the year ahead other than those caused by financial constraints. Labour has no plans for altering the present relationship between research councils and the research they sponsor, so for the time being the Rothschild restructuring will presumably be allowed to proceed. Labour likewise does not intend to implement the recent recommendations for student loans and for changing the emphasis to post-experience study for PhDs.

Finally, what of some of today's symbols? Concorde, child of the white hot technological revolution of the 1960s, will no doubt fly for BOAC and Air France and few else: this is a business decision and politicians will be glad to be rid of it. Maplin, London's third airport, will have to wait. And the think tank? One suspects it will stay, and that one or two of *Nature's* readers will end up in it.

100 years ago

IN a most interesting article on the planet Mars, in your issue of *NATURE* for Feb. 19, which has just been shown to me, the Rev. T. W. Webb directs attention to the question of the colours of Mars being due to effects of contrast or not, and says—"Nor does it seem to have been noticed that no effect of contrast has been traced in the Polar snows."

Kindly permit me to inform Mr. Webb that, in a paper on Mars in the last volume of the "Monthly Notices of the Royal Astronomical Society," I expressly state that, "on May 14, 1873, the south Polar ice appeared (in an 8½-inch silvered glass reflector, by Browning) of quite a pale sky-blue colour, evidently by contrast," and I may add that this effect I noticed also on two or three subsequent occasions.

Burton-on-Trent, March 12

EDWARD B. KNOBEL

From *Nature*, 9, 247, February 12, 1874.

Scientists' dispute is symptom of a deeper problem

Dr G. J. Leigh, of the Agricultural Research Council Unit of Nitrogen Fixation at the University of Sussex, expresses his personal views about the pay dispute involving British Civil Service scientists.

THE current agitation among Civil Service scientists is stimulated by comparisons of pay scales such as those in Table 1. Scientists have been in dispute with the Civil Service Department (CSD) for some four years but I shall not detail the history of the dispute here. Its resolution currently lies with the Pay Board but is not yet in sight. It is the CSD's opinion that the question is not one of relativities and Lord Windlesham has now implied that the government is not bound to accept the findings of the Pay Board. In November 1973, at the inception of Stage III, the CSD negotiated with indecent haste a pay settlement for about 400,000 civil servants, but excluding scientists, giving increases of nearly 20%, and there is a feeling among scientists that the CSD is conducting a vendetta against them. How else to explain the situation in which an officer with 3 A-levels can qualify for the Family Income Supplement?

The current situation is, however, a reflection of conditions which have existed for many years. The government employs more scientists than any other organisation in the country yet it is far from clear whether the government—any government—has ever had a coherent policy for science and technology other than allowing developments to occur by default. Any government of a modern state requires scientists to carry out routine tasks but it has been accepted for more than fifty years, since Haldane at least, that the British government should sponsor general long term research and have available a source of informed scientific opinion. Presumably this requires a pool of scientists of the highest quality. But although an individual can define areas in which he feels the government should be active, there is little indication that a government knows how it should use its scientists or even that it really wants to.

The 1964 Labour government talked about the white heat of technology but the only long lasting product of the

conflagration would seem to be Concorde. The 1970 Conservative administration carried through the Rothschild exercise. And it cannot be denied that any group which consumes large amounts of state money has to recognise that it is accountable to the state. Scientists are perhaps more cautious and conservative than most but the manner of introduction of Rothschild principles was not calculated to allay their apprehensions. One consequence was the creation of uncertainty among a large group of scientists who felt they were being forced into a new kind of organisation of which they did not necessarily approve. Another was to enlarge the bureaucratic machinery through which research projects must filter before being acted on.

Lord Rothschild did not attempt, however, to define the areas in which applied research should be carried out. He left the selection of work area to a rather artificial market mechanism such as has operated (sometimes with conspicuous lack of success) for defence contracts. Nor did he deal with pure research, which was outside his immediate terms of reference. Consequently, research programmes must become dependent on specific pressures from industry or ministries, and for that reason are likely to become primarily short term in nature.

Nevertheless, the Rothschild mechanism does represent a way in which a government could introduce a broad coherent policy covering both pure and applied research, and encompassing problems such as cancer, fuels or resources. It also implies a scientific Civil Service which has a properly developed structure in which problems such as pay relativities, short term contracts, transfer between Civil Service classes and career development in small research units, have been fairly resolved.

The reality is rather less encouraging. For example, one hears through the grapevine that there is money 'available' for research into energy and resources problems. It would seem that this will produce some postgraduate and post-doctoral research in a few university departments rather than be applied in a broad, considered approach to national problems. The response is too little, too timorous and probably too late.

The application of the Fulton principle of unified pay and grading in the Civil Service, which would solve many of the problems outlined, has been supported by both Labour and Conservative governments. Even while it has been official government policy, the consequence of the CSD's actions has been to make the implementation below the senior grades more difficult. Ministers have expressed deep regrets about the current situation but nothing more concrete has transpired. Consequently Civil Service scientists have become much more aware of the need to organise themselves and of the need to have a strong trade union,

TABLE 1 Relative pay scales for Civil Service groups at January 1, 1974 and numbers in post on April 1, 1973

Science Group	No.	Salary range (£)	Administration Group	No.	Salary range (£)
Principal Scientific Officer	2,140	4,895-3,715	Principal	3,778	5,775-4,360
Senior Scientific Officer	3,505	3,895-2,798	Senior Executive Officer	6,403	4,542-3,756
Higher Scientific Officer	3,904	2,854-2,221	Higher Executive Officer	19,996	3,585-2,953
Scientific Officer	2,898	2,329-1,410	Executive Officer	45,670	2,782-1,819
Assistant Scientific Officer	3,800	1,729-792			2,306-1,360
Subtotal	16,247		Total	75,847	
In fringe bodies (for example United Kingdom Atomic Energy Authority research councils)	11,206				
Linked grades (for example Patent examiners, Defence College lecturers)	4,501				
Total	31,954				

Experimental Officer and Scientific Officer and Assistant Scientific Officer are not exactly comparable

whether inside or outside the Trades Union Congress.

I have tried to show that the current pay dispute is only a symptom of a much deeper problem, which is how (and possibly whether) the government should use science and scientists. Certainly scientists will have to learn to be more adaptable but they cannot be treated as operatives

who perform a service to order. It is the duty of a government, through its science policy, to create the environment in which scientists can work constructively. It is in the interests of scientists and the community in general that the current impasse be resolved and not be allowed to re-develop.

Picture by Robin Laurance

Scientists on the march

FOUR thousand government scientists and a labrador dog, led by a jazz band playing the blues, made up the first major demonstration to converge on Number Ten, Downing Street, during Mr Wilson's latest tenancy. After a mass meeting at the Central Hall, Westminster, where striking scientists signalled their militancy with well ordered applause at their general secretary's every cadence, the demonstrators bore down on the Prime Minister, and at one stage their parade filled Whitehall from one end to the other. The occasion was the first national half day strike by members of the Institution of Professional Civil Servants (IPCS), whose campaign to force a decision on their long delayed pay claim happened to coincide with a general election campaign. Indecision over the state of the parties, and their relative abilities to form a government, left the scientists with a grand scale protest planned and no minister in office to enjoy the benefit of it. So they settled for Mr Wilson, who on a bright afternoon, to the strains of the St Louis Blues, received the following note:

"You will know that civil service scientists and those employed in fringe bodies have today been on strike in connection with the completely unreasonable delay in dealing with their long outstanding pay claims. This is the first occasion on which any group of the institution's members have taken national action of this kind, and it is the clearest possible demonstration of their dissatisfaction with the present position. At a meeting of scientists employed in the London area, at which something like 2,000 were present, the following resolution was carried: this mass meeting, representing thousands of scientists employed in the Civil Service and fringe bodies in the London area, expresses its deep sense of outrage that after three years of patient endeavour the government is still procrastinating on scientists' reasonable pay demands. It stresses the absolute necessity for immediate pay increases for scientists who are unique in having suffered a fall in living standards over the past three years and who are now at least 28% behind general pay movements. It urges the government to give priority to producing a fair and satisfactory solution to this urgent problem."

The Pay Board's report on scientists' pay, the delay of which caused the IPCS to mount a campaign of industrial action, is expected under the new administration to be published rather promptly. Not only does Mr Wilson have a distinct commitment to placate angry unions, but the Pay Board, whose future may well hang in the balance, does not have much else to work on these days. The SOS placard in the pictures is a new slant on a slogan which the outgoing government coined in order to save power during the miners' strike: "Switch off something". The electorate apparently got the message.

international news

Academy reports on Vietnam herbicide damage

Colin Norman, Washington

IN the late 1960s, United States military forces dumped nearly 19 million gallons of herbicides on an area of South Vietnam equal in size to the entire state of Connecticut or Northern Ireland. According to the National Academy of Sciences, the most prestigious scientific organisation in the United States, some of the sprayed areas could bear the scars of this massive chemical assault for 100 years or more unless swift action is taken to reforest the land. The academy has also reported that interviews with people living in the highlands of South Vietnam have produced extremely consistent reports that children and animals were killed by the herbicide sprays.

Those conclusions have emerged from an intensive study conducted by an international team of scientists which worked for three years under the academy's auspices. After much delay and considerable wrangling in the academy itself, the fruits of the team's endeavours were published last week in the form of a 400-page report* prepared for the Department of Defense and the US Congress. The document provides the most extensive and authoritative survey so far of the damage caused to the Vietnamese people and their environment by military herbicide operations, but it is unlikely to quell the bitter debate that has been going on in the United States about this aspect of the Vietnam war.

For one thing, the report is already being used by both sides to bolster their cases. The Department of Defense, for example, has put out a statement which invites the reader to draw the following conclusion from the report: "some damage has resulted from the military use of herbicides in Vietnam, however, most of the allegations of massive, permanent ecological damage are unfounded". On the other hand, it has been argued that

the academy has turned up evidence of damage so extensive that it provides a compelling case for a flat ban on the use of herbicides in war.

Another reason why the report is unlikely to dampen the debate is that the investigating team has failed, for a variety of reasons, to come up with a definitive answer to the most contentious question of all—whether or not the herbicide spraying caused an increase in the number of birth defects in communities that were particularly hard hit.

Finally, the team itself failed to reach agreement on how much destruction has been wrought on Vietnam's inland forests. This aspect, in fact, held up publication of the report, caused three members of the team to disassociate themselves from the final conclusion, and is sure to lead to a long dispute.

The report, nevertheless, is an extremely valuable document, not least because it is the first authoritative account of the extent and nature of the military herbicide missions flown over South Vietnam between 1965 and 1970. In all, nearly 9% of the area of South Vietnam received at least one dose of herbicide.

Working from a military record which gave details of the time, place, type and amount of herbicide sprayed, in conjunction with vegetation maps and aerial photographs, the academy team constructed a picture of the spray operations which indicated that 10.3% of South Vietnam's inland forests, 3.2% of the cultivated land, 36.1% of the mangrove forests and 5.5% of other areas in the country were doused with a variety of herbicides at least once.

In the total of nearly 19 million gallons of herbicide distributed over South Vietnam, the majority—11.22 million gallons—was so-called 'agent orange'. This is a half-and-half mixture of the herbicides 2,4-D (2,4-dichlorophenoxyacetic acid) and 2,4,5-T (2,4,5-trichlorophenoxyacetic acid). Use of this agent was terminated in 1970, according to the military records, because it had been suggested that 2,4,5-T may cause birth defects, and because it was found that the stuff was contaminated with a highly toxic chemical called TCDD (2,3,7,8-tetrachlorodibenzo-para-dioxin). The other two chief agents used were 'agent white' (2,4-D and Picloram) and 'agent blue' (sodium cacodylate, and arsenic compound).

According to the military records, about 88% of the spraying was directed at forests, 9% was aimed at destroying crops in areas under the control of the National Liberation Front (NLF), and about 3% as directed at the perimeters of military bases. But those figures underestimate the area of crops destroyed for a variety of reasons. For one, spray from defoliation missions tended to drift outside the target area on to crops; in fact, the report states that "in 16 out of 18 areas studied by aerial photography, crop damage by defoliation missions was greater, and sometimes considerably so, than by crop destruction missions". For another, the Montagnards (the highlanders) conduct much of their agriculture in cleared areas of forests, and so their fields were often sprayed during attacks on the inland forests. Finally, the report suggests that in some defoliation missions, herbicide was in fact sprayed directly on crops, although the investigating team is careful to say that their suggestion "is not intended as an expression of opinion as to whether or not the official policy on herbicide operations was violated".

The damage wrought by this assault varied considerably from one area to another, but the most severe and the most persistent destruction was suffered by the mangrove forests. The report indicates that a single spray attack on a mangrove forest was sufficient to kill all the trees directly hit, and some regions of South Vietnam have been completely denuded by repeated herbicide applications.

More than a third of all the mangrove forests in South Vietnam were directly sprayed, according to the records, and the report states that "large contiguous areas were devastated, and there has been little or no recolonisation of mangrove trees in extensive areas". The reason is that some regions, such as the Rung Sat zone southeast of Saigon, were so heavily sprayed that all the vegetation has been destroyed and no seed sources are left to colonise the area. The report states that "under present conditions of use and natural regrowth, it may take well over 100 years for the mangrove area to be reforested". A massive reforestation programme, however, could probably restore the mangrove forests in two or three decades.

Although those reports are bad enough, some observers have suggested

* *The Effects of Herbicides in South Vietnam*, Part A: Available from the National Academy of Sciences, 2101 Constitution Ave NW, Washington, DC 20418. \$10.

that they may even underestimate the extent of damage to the mangrove regions. Dr Matthew Meselson, a Harvard biologist who surveyed the effects of herbicide damage for the American Association for the Advancement of Science, suggested in a telephone interview last week, for example, that uncertainties about the extent of the area sprayed, drifting outside the target area, and other factors may have caused the academy team to underestimate the sprayed area by about 30%. In any case, Dr Philip Handler, President of the academy, points out in a personal introduction to the report that unless a vigorous reforestation programme is conducted in the mangrove forests "mankind will have been guilty of a large and ugly depredation of our natural heritage".

Although the academy team and other observers are in relatively close agreement about the massive devastation suffered by the mangrove forests, the effect of herbicide spraying on inland forests is open to considerable debate. Because much of the survey was carried out while the war was going on, and because even after the cease-fire was signed a considerable amount of fighting was still taking place, the academy team had to rely chiefly on aerial photography for its analysis of the destruction of inland forests. Under those conditions, little ground work was possible. Consequently, the data are not of the best quality, and their interpretation is, to put it mildly, a difficult task.

When the report was in one of its early drafts, it became apparent that the investigating team's estimate of the destruction was considerably below that of other observers and investigators who had surveyed the damage for themselves. The academy's Report Review Panel, a committee of academy members which screens publications before they are released, refused to accept the estimates, and instructed the team to take another look at the data. It later became apparent that the extent of damage was underestimated because little account had been taken of the fact that repeated herbicide applications killed the trees to a greater extent than the team had first supposed.

Three independent photointerpreters and forestry experts were called in to help with the analysis, and the report eventually came up with the suggestion that about 1.25 million cubic metres of 'merchantable' timber had been lost from the inland forests because of herbicide spraying. The report said that although the exact figure cannot be taken as Gospel truth, it almost certainly lies between 0.5 and 2.0 million cubic metres.

Two of the independent photointerpreters reckoned that the figure is probably near 2.0 million cubic metres, while the third said that it could be an order of magnitude greater. One of the team, Professor Pham-Hoang-Bo from Saigon University, dissented from the report because he believes that the estimate of damage to the inland forests is much

too low. Another member, Professor Paul Richards of the University College of North Wales, dissented for similar reasons. Professor Alexander Leighton of the Harvard School of Public Health, said that he couldn't go along with the conclusion because he has no expertise in the field. And Dr Meselson, who was a member of the report review panel, said last week that he believes that the report's estimate of tree damage understates the case by at least an order of magnitude.

Meselson pointed out for example that the report gives a figure for the density of trees in Vietnam forests which is considerably less than the density of trees on the front lawn of the National Academy of Sciences—a lush, very lightly wooded expanse of grass. He said that this shows that there is clearly something wrong with the interpretation of the photographs, and he would like to see the academy team brought back together "if they can bear it" to take yet another look at the data. In any case, he said that he intends to publish his own conclusions independently.

Whatever the final outcome of the debate about the extent of the devastation of the inland forests, the academy report suggests that in lightly sprayed areas, redevelopment will probably resemble the pattern of forest growth following harvesting of large trees. The more heavily sprayed areas are, however, another matter, and will require considerable help in reforestation. It is reckoned that about 12% of the total sprayed area will require a major assistance programme, but Meselson believes that the figure is considerably greater.

As for the effects of herbicides on the people of Vietnam, the academy team looked for toxicity to people directly exposed to the herbicides, birth defects in the offspring born to exposed mothers, economic effects from crop destruction, and the psychological effect of the whole military herbicide programme on the Vietnamese people.

The most disturbing accounts of damage from acute toxic effects came from interviews with Montagnard people who live in the highland regions. The interviews, mostly conducted by Dr Gerald C. Hickey of the Southeast Asia Program of Cornell University, produced remarkably consistent reports of death to children, diarrhoea, skin rashes looking like insect bites, and abdominal pain following spray missions. They also reported widespread deaths among their animals, particularly chicken and pigs, and they said that the spraying killed fish in the streams.

Dr Hickey said in a telephone interview last week that he first heard about the reports of deaths from Montagnards in refugee camps, but he later went into

Aerial photograph of damage to mangrove forest in Ca Mau Peninsula in southern tip of Vietnam. Photo taken in 1971 shows effects of individual spraying missions over the forest. (Reproduced by permission of the National Academy of Sciences.)

the villages to talk to the people in their own localities. The reports, he said very accurately described the spray planes, the effects of the herbicides on the vegetation, and the accountants of the toxic effects on humans were consistent from village to village. The report itself says that "reports of illness following spraying are so striking it is difficult to dismiss them as simply the effects of propaganda, high normal death rates, or faulty understanding of cause and effect".

Asked why the reports of death came mostly from the highland people, Hickey suggested a number of possible reasons. First, they were hit mostly with agent orange, perhaps the most toxic of the herbicides used in the military operations, particularly since it is contaminated with TCDD. Second, the defoliation missions wiped out their crops because their fields are mostly in areas of reclaimed forest, and this tended to increase exposure to the chemicals. Third, the Montagnards tend to live out of doors much more than the lowlanders do, and they carry their children on their backs when they work in the fields. Thus they would be more likely to be exposed to the herbicide sprays. And finally, the people repeatedly emphasised in their interviews that they "didn't know what was happening" when the aircraft started spraying, and many of the children drank contaminated water or ate sprayed crops.

Since the reports came from direct interviews with Montagnards, they are difficult to verify by independent means, but Dr Hickey, a world renowned authority on the Montagnard people, is extremely disturbed by them. He is also extremely disturbed by Dr Handler's personal introduction to the academy report, which labelled the accounts as "secondhand" and "tales". Handler also said that the committee regrets that it was unable to visit the Montagnards in their own regions to verify the reports. Hickey did, however, get his information firsthand (albeit with the help of interpreters), and he did follow up his investigations in the Montagnard villages. He said last week that he had no chance to see Handler's introduction, in fact he didn't even know it would be written, and said that he finds it "outrageous". He said that in his nine years in Vietnam, he has encountered innumerable attempts at covering up the damage wrought by the war, and that this "is another one of them".

As for the effects of herbicides on birth defects and stillbirths, the report explicitly states that the team "could find no conclusive evidence of association between exposure to herbicides and birth defects in humans". The basis for that comment was a search through the records of two major Saigon hospitals

which showed "no consistent pattern of association between rates of congenital malformations and annual amounts of herbicides sprayed".

But a more extensive study is being conducted on the records of the Childrens Medical Relief International unit (the so-called Barsky Unit) of the Cho Ray Hospital in Saigon-Cholon. The study is not yet completed, but the report says that so far there is no strong evidence for an association between herbicides and birth defects.

Two members of an earlier survey of the effects of herbicides in Vietnam, the AAAS study, said last week, however, that the team had not conducted as thorough a study as it could, and suggested that a follow-up is required. Dr John Constable, of Harvard Medical School and Massachusetts General Hospital, suggested that the academy team had failed to look more closely at the figures from the Saigon Children's Hospital, particularly in the years following the AAAS study. "They reexamined our figures", he said, "but they have not attempted to add figures of their own".

The AAAS study pointed out that incidence of cleft lip, relative to other birth defects in the records of the Saigon Children's hospital, showed a marked increase in the years 1966-1968, the years of heaviest herbicide spraying. Although the AAAS team, which was led by Meselson, was careful to say that this effect was not necessarily correlated with herbicide spraying, the figures at least bear close scrutiny. The fact that the academy team had not looked at data from the hospital in the years after 1970 is, according to Meselson, "disappointing".

If there is a teratogenic effect from herbicide spraying, it is likely to have come from the TCDD contamination in the agent orange. TCDD—which is often more familiarly referred to as dioxin—is an extremely potent teratogen in mice, and when it was discovered in 1970 that it is always present in 2,4,5-T, there was great consternation about the risks to Vietnamese people exposed to agent orange. The chemical is such a potent teratogen that it is feared that amounts too small to be detected may prove to be harmful if they get into the food supply.

Last year, however, Meselson and his colleague Robert T. Baughman, reported an extremely sensitive method for detecting TCDD, which they used to analyse fish samples taken from South Vietnam in 1970. They found levels of the chemical ranging from 0.0007 parts per million to 0.008 parts per million. They are now in the process of analysing fish and shrimp samples taken last year, and preliminary results indicate that there is still some contamination with TCDD. The academy committee considered

these findings to be "a matter which warrants further attention". Use of Meselson's method for detecting dioxin in the food supply would be an ideal basis for selecting populations to study for birth defects.

Although the academy's study will clearly spark off a considerable debate about the conclusions that have been drawn, there is no doubt that it has added a huge amount of information on one of the most contentious issues to arise from the Vietnam war. In fact the report published last week was only a summary of the data (even though it ran to 400 pages), and the academy intends to publish later this year all the documentation gathered together during the three years that the report was in preparation.

It remains to be seen whether this wealth of information is sufficient to build up a strong enough case to convince the Administration that herbicides should be banned from use in war. The United States has yet to ratify the Geneva protocol of 1925 which outlaws the use in war of chemical weapons. Ratification of the treaty is now being held up because the US Senate insists that the protocol covers herbicides and tear gases, while the Administration insists that it doesn't. Secretary of State Henry Kissinger informed the Senate Foreign Relations Committee last year that the Administration's position is under review. The academy study is likely to play a considerable role in that review.

Unfilled places

MORE than six thousand university places, mainly in science, engineering and technology subjects, went unfilled in Britain at the beginning of the current academic year. The figures are contained in the eleventh report of the Universities Central Council on Admissions (UCCA), the body which handles the applications of most intending students in Britain. According to UCCA, the British universities expected to receive 71,875 students in October last year, and in fact only 65,586 places were taken. The shortfall in engineering and technology was 1,991, and in science 3,198. In a foreword to the report, Chairman of the Council Dr Geoffrey Templeman says that although the figures contain an element of estimation, and therefore need to be used with care, the picture they reveal is "not encouraging".

Science policy changes in Canada

David Spurgeon, Ottawa

GOVERNMENT announcements seem able to confuse as often as they can inform, and such was the case with those made recently about the forthcoming changes in federal science bodies in Canada.

The announcements came in the Speech from the Throne at the opening session of Canada's 29th Parliament on February 27, and in press releases issued about the same time by the Ministry of State for Science and Technology (MOSST). Those in the throne speech informed only in the briefest and most general way, while the details offered by the ministry's press releases served mostly to confuse.

The throne speech said: "the Ministry of State for Science and Technology will be developing national science objectives as a basis for exercising enhanced advisory and co-ordinating authority within the government. Two new granting councils will be formed, one for social sciences and humanities and the other for natural sciences".

The ministry's press releases spoke in different terms: "the government plans to strengthen the Ministry of State for Science and Technology in order to ensure a more efficient use of human resources and scientific activities in the pursuit of national goals", said one. "Its (the ministry's) advice will increasingly be taken into account by Cabinet, in relation to new science oriented policies . . ." said another, labelled statement by Mme Jeanne Sauve, Minister of State for Science and Technology. "Its impact will also be markedly increased in relation to the assessment of scientific programs and associated expenditures. Close cooperation between the ministry and Treasury Board is developing in these areas and it is the intention to focus attention, not only within the government itself, but also in the public domain on the distribution and extent of expenditures in science".

The question in the minds of some was whether the changes outlined meant that the ministry was finally becoming what they had feared it might become—an all-powerful monolithic instrument of power in Canadian science policy—or whether its statements only gave that impression.

That they did give that impression was confirmed by a quick sampling of early reactions among scientists who had read the press releases or news stories about them. Such reactions ranged from expressions of fear and concern to outright predictions of gloom and doom for the future of science in Canada. The

doomsters saw the moves as a political power play by the fledgling ministry, which they feared would create a super-bureaucracy concerned with administrative efficiency and political expediency rather than the good of science or its judicious application.

But those closer to the federal bureaucracy saw things differently. The realities of the situation meant that such a consolidation of power by the ministry was impossible even if desired, they contended, and the politics of the scientific establishment would assure that there is no cause for apprehension.

The changes outlined clearly in the science ministry's press releases were these:

- The granting function of the National Research Council will be separated from the NRC laboratories and removed to a new council entitled the Natural Science Research Council.

- The granting function for the social sciences and the humanities will be removed from the Canada Council and established in a new granting council to be called the Social Sciences and Humanities Research Council. The Canada Council will continue to remain responsible for support of the arts.

- The Medical Research Council's granting functions will remain undisturbed, but the MRC will be placed into "an appropriate relationship" with a new Inter-council Co-ordinating Committee.

- This new Inter-Council co-ordinating Committee will be established by the government to advise on allocation of funds among the granting councils; ensure coverage by the councils of all recognised disciplines; standardise granting practices; ensure that the needs of inter-disciplinary research are met; and coordinate and advise on council programmes—as well as those of federal government departments—in support of university research.

- The new committee will be chaired by the Secretary of the science ministry and will report to the Minister of State for Science and Technology.

- The science ministry will be involved in development of a science policy framework to provide guidance on scientific activities to all departments and agencies in terms of science objectives, priorities and strategies; the development of science expenditure guidelines for science agencies and the Treasury Board; for collaborating with the Treasury Board in analysing expenditures and programme proposals; and in annually assessing accomplishments of government science activities.

Some saw in these moves control by the ministry of the granting agencies and a pre-eminent position for the ministry in directing the use of fiscal sup-

port for science. This seemed to be confirmed by further announcements that the Science Council of Canada Act would be amended to give the council a more public role, while the ministry would take over its former role as official science advisory body to the federal government.

The announcements were also seen as evidence that the government had taken seriously the recommendations of the Senate Special Committee on Science Policy (the so-called Lamontagne Committee), which in its report No. 3 had said that the science ministry's advisory role was not good enough for its survival, and that "sooner or later MOSST will face a dead end unless it is given more authority . . . the committee believes that the Ministry of State for Science and Technology should become the focus of a central machinery for the concentrated planning and control of government involvement in science and technology".

Where the confusion arose was in certain ambiguities—and certain omissions—in the ministry's press releases. For example, while the press releases referred to the past reporting practices of the NRC and MRC and Canada Council, they avoided saying explicitly where these agencies might report in future, while making it easy for the reader to conclude that this would be, in effect, to the Minister of State for Science and Technology through the new Inter-council Co-ordinating Committee.

In fact the NRC and MRC are both Crown corporations and the Canada Council is a foundation, which report to Parliament through the President of the Treasury Board (NRC), the Minister of National Health and Welfare (MRC), and the Secretary of State (Canada Council). Changes in legislation would be required to change this, and nothing in the throne speech presaged such changes. The heads of the MRC and Canada Council are known to understand that their respective reporting procedures will not be changed. And it seems illogical that a humanities council head would report to the science minister, though the ministry press releases are silent on this point. Nor do they say to whom the new Natural Sciences Research Council will report.

Equally vague are the references to the relationships of the granting councils to each other and to the science ministry as members of the new co-ordinating committee. Even the make-up of the committee is left a mystery: it "will include in its membership, the heads of the granting councils and certain other senior officials to be named later".

Old Ottawa hands see all this as a struggle for power by the science ministry, but a struggle with an extremely uncertain outcome. Concerning the con-

tinued autonomy of the granting councils, which is seen as crucial to the future of science in Canada, a great deal will depend on the way the Inter-council Coordinating Committee works, and this in turn depends greatly on its membership and the effectiveness of its chairman.

The possibility of the ministry using its enhanced position as government science adviser and budgetary watchdog as a path to massive centralisation of power is also seen as unlikely, given the realities of the situation. The science minister is not a member of the Treasury Board and has not the political heft of huge science-related departments like Environment. Nor need the Treasury Board heed the ministry's advice unless it finds it good—it has its own advisers as for other areas, and conducts its own assessments, and will continue to do so. Or so runs the argument.

Whatever the outcome, some observers are wondering what happened to another major recommendation of the Lamontagne report (and one made by other studies): the need for a better linkage between government R&D and industry. None of the re-organisational changes seem bent toward this goal—and in fact the splitting of NRC's laboratories from the granting council (which provided such a link) seems actively to work against it. The NRC laboratories, it seems, will be isolated.

Velikovsky in the open

Miranda Robertson, San Francisco

THE scientific session on the heterodox theories of Immanuel Velikovsky at the meeting of the American Association for the Advancement of Science (AAAS) in San Francisco on February 25 was the first and probably the most serious of four symposia to be held this year on various issues raised by Velikovsky's ideas and his attempts to propagate them. The organisers of the AAAS symposium adopted the stance that Velikovsky has offered a 'challenge to science'. Science, in the persons of Dr P. J. Huber (Swiss Federal Institute of Technology, Zürich), Dr J. D. Mulholland (University of Texas) and Dr C. Sagan (Cornell University) rose to meet it.

The only remarkable thing about the resulting session was the amount of time and energy Drs Huber, Mulholland and Sagan had been prepared to put into it. There seems little danger that any real scientist or scholar would be tempted to take Velikovsky's ideas seriously. Best-selling books are usually fiction, and Velikovsky's *Worlds in Collision*—

published in 1950 by Doubleday after the Macmillan Co., showing more academic integrity than business acumen, had passed it on to them—is plainly no exception. Velikovsky himself is by birth a Russian Jew trained in medicine and psychiatry.

Ostensibly, the fundamental issue at the symposium was Velikovsky's version of the birth of Venus. His story is that the planet originated as a comet torn out of Jupiter about 1500 BC, when it went into an eccentric orbit in which it narrowly missed the Earth a number of times and disrupted the orbit of Mars before settling down about 800 BC in its present position in the solar system. All this is documented in the Bible (the seven plagues of Egypt, the Israelites' manna from Heaven and various other miraculous phenomena were the consequences of cosmic catastrophe) and in some ancient Egyptian writings.

Huber was brought in to deal with Velikovsky's Egyptology and Assyriology, Mulholland to tackle his celestial mechanics, and Sagan to do battle energetically on all available fronts at once. Velikovsky, however, turned out to be too easy to discredit. He muddles his myths, confusing Athene and Aphrodite; and his chemistry, confusing carbohydrates with hydrocarbons—so that Venus at once bestows upon the Earth supplies of petroleum (hydrocarbon) and manna for the children of Israel (carbohydrate) from its atmospheric clouds, now known in any case to consist of sulphuric acid. The spin resonance of the Earth with Mars and Venus can only be explained by the stability of all three planets in orbit in the solar system for billions of years. Cuneiform texts reliably dated well before 1500 BC refer to a Venus behaving recognisably as Venus behaves today.

Velikovsky replied to his critics with rhetoric not reason. The issue, in short, was not scientific but sociological. Indeed it was stated at the beginning of the session by Dr N. Storer, who is a sociologist at the City University of New York: in principle, the progress of science depends on the patient and impartial evaluation by the scientific community of all new ideas and work. In practice, no-one has time to examine the arguments of every heterodox claimant to new insights and it is surprisingly easy to be certain in the majority of cases that one is not withholding recognition from a second Einstein.

Velikovsky, however, claims not merely to have been ignored but to have been unfairly attacked by the scientific establishment. This was the real burden of his challenge, and the attempt to deal fairly and seriously with his thesis succeeded in illustrating exactly what makes scientists lose patience with the majority of far-reaching new theories. Generally,

they are so loosely stated as to present inadequate premises for logical or quantitative reasoning. This point was emphasised by Dr Sagan, both explicitly and implicitly in his struggle to find the substance of Dr Velikovsky's theories.

For Sagan—himself no mean propagator of wild theories, as might be inferred from his editorship of the journal *Icarus*—the professed object of the apparently unedifying exercise in San Francisco was the demonstration of the essence of scientific method, and what happens when its criteria are applied to fantasies such as Velikovsky's.

Actually, like the symposium on unidentified flying objects held by the AAAS five years ago, it was an exercise in setting the record straight. The sensational speculations are made available to everyone by the popular press, but where are people to find the sober evaluations? Sagan has suggested that this should be an occasional but regular function of organisations such as the AAAS. In many ways this seems a more plausible justification for unweildy annual science meetings than the pretence that they do anything to further the cause of science. Furthermore, the subject matter for the meetings would thus be selected by an entirely democratic process, since the only criterion for including a subject in the agenda for discussion would be the amount of public interest it had aroused. Whether the public actually wants to be disabused of sensationalist notions is, of course, another matter.

Seeing double

ANOTHER curious piece of programming by the BBC on Monday March 4 produced "Horizon" on BBC2 telling us that "The Future Goes Boom!" immediately followed by "What on Earth... are we doing?" on BBC1 in which Dr David Bellamy told us that we might just struggle along if we all tighten our belts. A more fruitful approach might have been to confront Professor Hermann Kahn, the prophet of boom, with Bellamy to thrash out the issues. As things stand, the protagonists are about even; both programmes opened with film of an Apollo launch, but the print used by the "Horizon" team was much sharper and in better colour. To balance this, Bellamy's subsequent down-to-Earth approach made more sense than Kahn's frenetic globe trotting while calculating, apparently on the back of the proverbial envelope, just how many people are likely to be killed in the forthcoming nuclear war. But a solid 2½ hours of proselytisation with no lucid discussion or pause for thought probably turned most viewers completely off, if they did not first turn it off.

news and views

When the lunar crust formed

THREE distinct aspects of lunar history have been dated from age determinations of rocks from the Moon. The basaltic lavas filling the visited maria sites have ranged in age from 3,100 to 3,900 million years. These lavas were produced by melting or partial melting of rock in the interior of the Moon by heat generated by the radioactive decay of uranium and thorium. The implied absence of younger rocks over a substantial part of the lunar surface is explained in part by the concentration of radioactive heat sources in the outer regions of the Moon which, coupled with the smaller size of the Moon, makes for a more efficient heat loss than is the case for the Earth. Internal motions within the lunar interior have been unable to disrupt the relatively thick crust and in consequence there have been no large scale horizontal movements of the crust to assist the process of continuing lava extrusion, again in contrast to the Earth. In general the lavas have been extruded into large, impact-generated basins, possibly along lines of weakness related to the impact.

An earlier episode of lunar history is represented by the dating of the complex fragmental rocks from the various highland sites. The ^{40}Ar - ^{39}Ar and Rb-Sr (mineral isochron) ages of highland rocks are, with a few exceptions, confined to a narrow time interval from 3,900 to 4,000 million years, indicating that the rocks were last at elevated temperatures at this time rather than that this is when their individual components crystallised. The ages have been taken by several authors to indicate the times when a number of the large impact basins were formed but there is no consensus as to how many basin-forming events are represented in the ages, and estimates vary between two (Orientale and Imbrium) and six (Orientale, Imbrium, Crisium, Nectaris, Humorum, Serenitatis). All authors are agreed that the first 500 million years of lunar history has been obscured by the intense bombardment of the highlands.

Evidence for the earliest period of lunar history has so far come from a comparison of the isotopic composition of Sr and Pb in suites of rocks from the various sites, in the lunar soil, and in one particularly exotic rock, 12013, from Apollo 12. All of these rocks have been subjected to reheating or melting at or more recently than 4,000 million years ago, but it is possible to draw inferences about the isotopic composition of the precursor material and specifically to show that regions of distinct chemical composition (differing Rb/Sr and U/Pb ratios) existed as early as 4,500 million years ago. The physical implication of this is that melting and the separation of chemically distinct rock types must have begun as early as 4,500 million years ago—shortly after the Solar System formed. The heat source responsible for this early melting is not clear although the gravitational potential energy released in accretion would be adequate if accretion were sufficiently rapid.

In the article on page 199 of this issue of *Nature*, Jessberger, Huneke and Wasserburg have used a third technique, the ^{40}Ar - ^{39}Ar method, to find evidence of relict crustal material in a 4,000 million-year-old breccia. The ^{40}Ar - ^{39}Ar method is a modified form of K-Ar dating first applied at the University of Sheffield to the dating of lunar samples from Apollo 11. It is a neutron activation technique which con-

verts some of the potassium in the rock to ^{39}Ar , and the age can be determined from the ($^{40}\text{Ar}/^{39}\text{Ar}$) ratio in the gas extracted by heating the sample at a succession of increasing temperatures. The method is in principle able to detect variations in the ($^{40}\text{Ar}/\text{K}$) ratio which could result from partial argon loss in a sample with a complex thermal history and in suitable circumstances to unravel that history.

Jessberger, Huneke and Wasserburg have applied the technique to separated minerals from a highland breccia which previously had been shown by Rb-Sr measurements to have been heated 3,980 million years ago but to temperatures insufficient to homogenise the Sr isotopic composition. The ($^{40}\text{Ar}/^{39}\text{Ar}$) ratios measured in a heating experiment of 30 to 50 steps correspond for the most part to this age of 3,980 million years, apart from small variations which seem to be an artefact of the technique, possibly related to the recoil of ^{39}Ar during neutron activation. In the highest temperature extractions from a sample of the plagioclase which showed the anomalous Sr isotope composition, however, the ($^{40}\text{Ar}/^{39}\text{Ar}$) ratio increased to a value corresponding to 4,500 million years. This would seem to indicate that when the breccia went through the heating episode at 3,980 million years most of the preexisting ^{40}Ar was driven off, except in some very retentive crystal sites in the plagioclase, and that the argon in these sites is retaining a memory of when the plagioclase originally crystallised as part of the early lunar crust, 4,500 million years ago. Thus all of the radioactive clocks now provide independent evidence that the crust of the Moon was beginning to form a very short time after the Solar System itself formed.

G.T.

From genes to behaviour

THERE is many a potential intermediary process twixt the gene and the behaviour it affects. This has been a general problem facing behaviour geneticists as they search for clues on the mechanisms of gene action. Sometimes the answer has been boringly obvious—the mutant mouse which builds nests larger than normal turns out to have thinner fur, and so on. But a number of the older studies on genes affecting nest cleaning behaviour of honeybees (Rothenbuhler, *Am. Zool.*, 4, 111–123; 1964) or courtship displays of *Drosophila* (Bastock, *Evolution*, 10, 421–439; 1956), for example, revealed effects which could reasonably be explained only by action on the central nervous system. There is, of course, no shortage of neural elements as potential sites for primary gene action, and for complex behaviour patterns it is difficult to take the story further.

The past few years have seen some important developments in behaviour genetics, relying on the identification of behaviourally-effective mutants induced in *Drosophila* and nematodes. The philosophy behind such work contends that behaviour genetics must be built from the bottom upwards, concentrating first on the simple behavioural repertoire of organisms with simple nervous systems.

Brenner and his group at Cambridge have progressed further than most with their nematode *Caenorhabditis elegans*, which has a nervous system of only a few hundred elements. A series of mutants which affect the worm's locomotion have been identified and some of these produce detectable and pre-

cisely regular defects in neural interconnectivity. Some of these defects are confined to one or two neurones whereas others affect every one of a series along the worm's body.

The regularity of nematode structure allows a finer-scale of analysis than is yet possible with *Drosophila*. Hotta and Benzer (*Nature*, **240**, 527-535; 1972) have used an elegant technique involving genetic mosaics to localise the site of action in their *Drosophila* behavioural mutants. They can definitely ascribe some of these to the brain alone, but so far only Ikeda and Kaplan (*Proc. natn. Acad. Sci. U.S.A.*, **66**, 765-772; **67**, 1480-1487; 1970) have pinned down a neural site precisely. One of their *hyperkinetic* mutants, which shows abnormal leg movements under ether anaesthesia, has modified spontaneous activity in specific motoneurones lying laterally in the thoracic complex. Not only have Ikeda and Kaplan been able to isolate these neurones from inputs and show that they retain the abnormal pattern, but they have used the most perfect control for systematic effects—a left/right mosaic in which the normal left half of the body can be compared with its mutant right.

On the sensory side Benzer's group, and others, have isolated several mutants which affect the electroretinogram response of the *Drosophila* eye. Most of these were picked up by screening the responses of large numbers of flies to various visual stimuli. Eyes are complex and mutants affecting the chemical senses have the advantage of a much simpler neural substrate. Ward (*Proc. natn. Acad. Sci. U.S.A.*, **70**, 817-821; 1973) has already described some genes affecting the chemotactic responses of *Caenorhabditis*. Kikuchi (*Nature*, **243**, 36-38; 1973) found a dominant in *Drosophila* which caused flies to be attracted by chemicals which repelled normal individuals. Now in this current issue (page 243) Isono and Kikuchi describe another autosomal recessive with a specific effect on the chemosensory hairs of the labellum (and presumably also those on the tarsi) which respond to sugars. In particular the mutation greatly reduces the response to glucose. Such a mutant should prove useful for the identification of receptor sites for sugars at the hair tip.

Slowly a catalogue of behavioural mutants is being built up. The bricks are few and the wall to be constructed is of enormous dimensions, but soon one may be able to detect some pattern in the brick laying. Nevertheless, those working with complex behaviour will have to wait some time for explanations of behavioural potential in genetic terms.

A.M.

Capping related to type of cell

TREATMENT of lymphocytes at 37° C with low concentrations of reagents such as concanavalin A or anti-immunoglobulin antibody leads to movement of the binding sites into large patches known as 'caps'. It now seems that the situation established previously is by no means a biologically homogeneous event. Stackpole, Jacobson and Landis show convincingly on page 232 of this issue of *Nature* that the exact location on the cell surface at which a cap forms depends in a critical and as yet undetermined manner on the type of cell and to some extent on the particular surface molecules being capped. Caps can form over or opposite to the Golgi region of the cell. Pinocytotic vesicles are seen only when the cap is formed over the Golgi region. Furthermore the new results may help clarify several puzzling and conflicting observations of the effects of drugs such as cytochalasin B on cap formation.

Caps are formed in the classical way by first exposing mouse thymus or spleen cells to specific mouse alloantibody directed against a particular surface membrane antigen and this is followed by cross linking with anti-mouse immuno-

Are supernovae disruptive?

It is arguable that all supernova explosions occur in binary systems, as a result of mass transfer between close companions. It is also arguable that all pulsars are created in supernova explosions. So the lack of any evidence to show that any pulsar is a member of a binary system looked at first sight embarrassing, and led in turn to the suggestion that supernovae always disrupt the binaries which give them birth. But the more recent discovery of X-ray 'pulsars' which are members of binary systems has encouraged a retreat from this extreme position; on page 208 of this issue of *Nature* Sutantyo shows that present theories of stellar evolution do indeed suggest that supernovae occurring in close binaries need not be disruptive in all cases.

It is interesting to speculate that this work may form the basis of a theoretical understanding of why some binaries should explode to produce variable X-ray sources, whereas others are turned into pulsars. As Sutantyo points out, the known X-ray binaries each contain an OB supergiant with mass some tens of solar masses, with a companion of around 0.5 to 5.0 M_{\odot} ; the large mass ratio suggests that the explosion occurred before mass transfer. In that case, the less massive star is probably the one involved in the explosion, and all such binaries with periods larger than 5 d remain bound after the explosion. That is more than 50% of all such systems.

Perhaps, as Sutantyo suggests, the only reason that radio pulses are not visible from such binaries is that the radio emission is absorbed and smeared out by the gas flows between the two stars. Any remnant which is left on its own by a disruptive explosion cannot remain an X-ray source for long, since this energetic emission requires a constant input of gravitational energy released by mass transfer between the components, according to the best theories. So such unattached remnants would inevitably be seen as radio pulsars, if they were seen at all.

And that, of course, raises the question of whether such sources are merely the minority cases from the explosions considered by Sutantyo (which seems unlikely in view of the number of pulsars known) or whether other kinds of binary system are indeed more often disrupted than not as a result of supernova explosions. Certainly there is more than one kind of supernova; do the different kinds produce different offspring?

J.G.

globulin antibody. Stackpole *et al.* used hybrid anti-mouse IgG/anti-ferritin antibodies that are revealed on the cell surface by adding ferritin. In this way it was found that a very high proportion of spleen cells display a cap of ferritin and this indicates, of course, a similar distribution of the underlying cell surface antigen. Almost without exception the caps were located over the Golgi elements of the cell when surface immunoglobulin molecules or concanavalin A receptor sites were capped. By contrast capping of H-2 antigens on mouse spleen cells is not polarised but patches form over and opposite to the Golgi region. A clear difference is seen with mouse thymus cells compared with spleen cells: in the first place Thy-1 and TL alloantigens capped predominantly over the Golgi region in spleen cells, whereas the Thy-1 alloantigen of thymus cells, for instance, is moved into the opposite pole of the cell.

It was shown previously by several groups that cap formation is often accompanied by pinocytosis of labelled membrane. After a relatively short period at 37° C cells may have much of their ferritin label within the cytoplasm and attempts to relabel the surface with reagents specific for the internalised receptors give negative results. It seems that pinocytosis takes place only in the special case in which caps form in the vicinity of the Golgi apparatus. Thus, caps of Thy-1, surface immunoglobulin or concanavalin A binding sites on mouse spleen cells are extensively internalised. In thymus cells very little pinocytosis of labelled surface markers takes place.

Stackpole *et al.* can distinguish further the two types of capping by the effects of certain inhibitors. General inhibitors such as sodium azide (and probably dinitrophenol) inhibit capping of all antigens both in spleen and thymus cells, but cytocholasin B has an effect only on the movement of antigens towards

the pole of the cell immediately adjacent to the Golgi apparatus. The drug therefore has almost no effect on capping of H-2 antigens on spleen cells, and redistribution of thymus cell surface markers is also not inhibited. In agreement with earlier studies, reagents affecting cellular microtubules, such as colchicine, vinblastine and colcemid, do not inhibit either type of capping. Indeed according to Berlin *et al.* (*Nature*, 247, 45-46; 1974) colchicine in certain conditions even facilitates capping of concanavalin A receptors. The effect of cytocholasin B, however, does suggest that at least one form of capping is actively dependent on intracellular contractile elements.

The way in which the direction of capping is controlled for a particular surface marker—for example H-2 antigens in spleen cells—remains to be determined. Clearly, the situation is very complex and many cellular processes providing multiple target sites for drugs are probably involved. R.C.H.

Translational repression

from a Correspondent

It is well known that the coat protein of group I and III RNA bacteriophages can act as repressors of the synthesis of the replicase by binding to their homologous RNA. Three reports in *Nature* this week (see pages 204, 223 and 225) by Steitz and two groups of collaborators shed fascinating light on the details of this process. Two of the papers are concerned with the secondary structure of the fifty-nine nucleotide-long segment of R17 RNA which is protected against T_1 nuclease attack by the coat protein and which has been sequenced. It contains the end of the coat protein gene including the tandem terminator and extends through the intercistronic region to the initiator region of the following replicase gene. Inspection of this sequence has suggested the presence of two helical regions, A and B; the first involves the coat protein terminator and the second the replicase initiator region.

Gralla, Steitz and Crothers from Yale have studied the melting behaviour of this fragment and demonstrate that differential melting curves exhibit two sharp peaks indicative of two substantial helical regions. Analysis of the details of these peaks allows estimations of the T_m and enthalpy of melting of these two helices. These estimations are in good agreement with the values calculated for the two helical regions A and B by methods worked out by the same group and assuming that helix B melts at the lower temperature.

This assignment of the lower melting peak to helix B is confirmed by the

work of Hilbers, Shulman, Yamane and Steitz from the Bell Telephone Laboratories who have studied the nuclear magnetic resonance (NMR) spectrum corresponding to the ring NH protons which are involved in the formation of A-U or G-C pairs. Their data suggest that at 26° C there are sixteen base pairs of which eight are no longer apparent at 40° C. A detailed analysis of the NMR spectra in terms of sequence-dependent ring current shifts suggests that the eight base pairs that are lost on increasing the temperature are derived from helix B. The disappearance of the signals corresponding to these base pairs does not necessarily imply that the helix is melted completely by 40° C but only that the mean lifetime of a base pair is less than about 5 ms. Indeed the data of Gralla *et al.* suggest that both helices are essentially intact for most of the time at 25° C in the presence of moderate concentrations of cations.

Gralla *et al.* went on to study the kinetics of the melting processes by temperature jump techniques. These measurements give time constants for these processes and also their amplitudes. As the temperature was increased from 25° C, a rapid process was observed with an amplitude that increased to a maximum at the lower T_m . Thereafter this amplitude decreased and was replaced by a slower process with an amplitude that increased to a maximum at the higher T_m . Clearly these two processes reflect the independent melting of two helical regions.

In further studies, Gralla *et al.* found by sedimentation equilibrium measurements that the molecular weight of a complex of the coat protein and this fragment reached a plateau value for a 1:1 mixture. Melting studies of this 1:1 complex revealed that although the T_m of neither helical region was altered by binding of the coat protein, the rate of melting of the lower melting helix B was reduced by a factor of 100 while that of helix A was unchanged. After considering various alternative hypotheses, these authors favour an interpretation that involves the binding of helix B to the coat protein and some irreversible process, perhaps involving the denaturation of the protein at the T_m of the helix.

That the coat protein recognises the B helix is further confirmed by the work of Steitz in the third paper who found that the coat protein will also bind to a twenty-nine nucleotide-long portion of the larger fragment which incorporates the B helix but not the A. Furthermore, an oligonucleotide from the turn of the B helix will not bind efficiently and this suggests that the B helix itself is recognised by the coat protein. Steitz points out that the sequestration of the initiator region in the B helix could account for the inability of *Escherichia coli* ribosomes to recognise the replicase initiator region.

It is emphasised by the authors of these papers that these helical regions may not exist in the intact R17 RNA at all times, especially when ribosomes do succeed in recognising the replicase initiator region.

Ice cover and global weather shift

by our Cosmology Correspondent

"Snow and pack-ice cover in the northern hemisphere formed earlier in the year and covered a larger area in the past 3 years than it did 7 years ago, when systematic satellite mapping began. This shift, in all likelihood, has produced a significant change in the hemispheric heat balance. The difference was most pronounced in the fall and was especially large in 1971. The anomalous global weather patterns of 1972 and 1973 may be the result of these developments."

That is the conclusion reached by G. J. and H. J. Kukla after studying weekly maps supplied by the US National Oceanic and Atmospheric Administration (NOAA) and based on photographs obtained by meteorological satellites. All snow and ice fields lasting more than 5 days are recorded on these photographs. The dramatic implication of this work is that with a better understanding of how the Earth's atmosphere

works, the changes which have caused such trouble in the northern hemisphere recently (and indeed those which are causing trouble in Australia now) might have been predicted in time for effective action to be taken.

As Kukla and Kukla point out (*Science*, 183, 709; 1974), the location and duration of snow and pack ice fields are the most important seasonal factors which affect the Earth's heat balance. Because of the heat required for melting snow and ice, peak air temperatures in summer at mid-latitudes are delayed after the peak insolation. In the northern hemisphere, permanent ice covers some 10×10^6 km², and seasonal ice and snow covers a further 50×10^6 km²; in the south, the corresponding figures are 14×10^6 km² and 20×10^6 km². The 'temporary' cover in the north is greater, of course, because of the presence of continents on which the snow can lie. Satellite mapping provides the only reliable means of monitoring the changing ice patterns over a whole hemisphere.

These studies are facilitated by dividing the year into four snow cover (SC) seasons. SC summer is the part of the year when less than 15×10^6 km² of

the northern hemisphere are covered; SC winter the period when more than 55×10^6 km² are covered. During the past 7 yr, SC winter and SC summer have been about the same length, averaging 80 to 90 d. But SC spring was, on average, about 7 weeks longer than SC fall. And the date on which SC fall and winter started were earlier in each of the successive years 1971, 1972 and 1973. In 1971, the change was dramatic, with SC fall starting 3 weeks earlier than in any of the 4 preceding years.

During the same period, there was a gradual increase in snow and ice cover found during the October/November period. For the entire 7 yr of this study, the average annual coverage was 34.9×10^6 km²; in 1971 alone this increased by 12% and since 1971 the average has fluctuated about a new mean of 36.9×10^6 km². On November 1, 1973, the cover was 36.7×10^6 km². So the period since 1967 divides naturally into two distinctly different sections.

Kukla and Kukla discuss at some length the possible sources of error in their study, and argue a convincing case that the effect they report is real. "There is no doubt", they say, "that the surface heat exchange in 1971 must have dropped

markedly". It is still too early to say definitely that this caused the change in global circulation which has, in recent months, been the subject of a great deal of discussion both in these pages and elsewhere; but it may well be significant that the changes in ice cover occurred before these changes in circulation became apparent. It seems plausible, at least, to argue that the observed changes in mean temperature and other parameters during the past 30 yr eventually produced the increased snow cover which has in some way disturbed the atmospheric circulation.

Superfluid ³He confirmed

from our
Condensed Matter Correspondent

THE report in a recent issue of *Physical Review Letters* (32, 141; 1974) by Kojima, Paulson and Wheatley of the University of California at San Diego that they have observed the propagation of fourth sound in the two newly discovered phases of liquid ³He amounts to the first unequivocal evidence that both of these new phases are superfluids.

It has long been known that liquid ⁴He is superfluid below its transition temperature at about 2 K but, until 1972, it was part of the conventional wisdom that the other isotope, ³He, was not a superfluid. This was mainly because of the theoretical impossibility that liquid ³He, whose atoms contain an odd number of fundamental particles and are called fermions, could become superfluid in the same manner as liquid ⁴He by undergoing a Bose-Einstein condensation; this phenomenon can only occur in assemblies whose components, bosons, contain an even number of fundamental particles. It was realised, however, that the electrons (also fermions) in a superconductor, at that time the only other known superfluid, acquired their superfluidity in a somewhat different way from ⁴He; and it had been suggested that a transition analogous to the superconducting transition in metals might occur in liquid ³He at a sufficiently low temperature, leading to some sort of superfluid state.

The first indication that this suggestion might indeed have been correct came some fifteen years later when Osheroff, Richardson and Lee of Cornell University discovered that two quite separate phase transitions occurred in a cell containing a mixture of liquid and solid ³He when it was cooled under pressure below 3 mK (*Phys. Rev. Lett.*, 28, 885; 1972). In subsequent experiments, Alvesalo, Anufriyev, Collan, Lounasmaa and Wennerström of the Technical University at Helsinki used

Synthesis *in vitro* of silkworm ecdysone

from our Insect Physiology Correspondent

TWELVE months ago some of the queries that have arisen concerning the site of synthesis of ecdysone in insects were discussed (see *Nature*, 242, 86; 1973). Briefly, the problem has been that, in spite of the conclusive experimental evidence (provided originally by Fukuda) that the moulting factor of insects is produced by the prothoracic glands, it has not proved possible to get convincing proof that the product ecdysone as isolated by Karlson and Butenandt is synthesised by these glands. Only the most minute amounts of ecdysone from the prothoracic glands have been extracted, and glands maintained *in vitro* produced only insignificant amounts of the hormone.

A group of Japanese workers led by Chino (*Science*, 183, 529; 1974) have now reinvestigated this problem and have found, as earlier workers had done, that the isolated prothoracic glands of the silkworm *Bombyx* maintained in the culture media of Grace or of Wyatt produced only minute amounts of ecdysone (less than 5 ng per pair of glands). Unchanged haemolymph blackens and is an unsatisfactory medium; but by isolating the haemolymph proteins on a Sephadex column and suspending these in Wyatt's culture medium and saline Chino and his colleagues attained a far more satisfactory "haemolymph medium". Arguing that the rich tracheal

supply of the glands indicated a high oxygen requirement for synthesis, they exposed the gland pairs, each pair in a single drop culture, to oxygen instead of air. By these combined procedures the hormone produced per gland pair increased in amount from 5 ng to 120 ng.

It is well known that the insect requires cholesterol for ecdysone synthesis. The authors therefore concluded that the lipoproteins of the haemolymph are likely to be the essential component so they then purified the two chief lipoproteins I and II from the haemolymph and prepared a culture medium by addition of these to Wyatt's medium—and this proved even more effective than the haemolymph medium. The hormone synthesised by the glands is at once liberated to the medium; in agreement with earlier observations, almost no ecdysone can be extracted from the glands themselves. Thin layer and gas chromatography established that the hormone produced by the glands is solely α ecdysone; as had already been suspected the more active and more polar product, β ecdysone must be formed from α ecdysone elsewhere in the body. Chino *et al.* report that another research team in the laboratory of Gilbert, working independently, has obtained similar results with the prothoracic glands of the tobacco hornworm *Manduca sexta* (*Proc. natn. Acad. Sci. U.S.A.*, in the press).

a vibrating wire viscometer to show that the viscosity of the liquid fell rapidly with decreasing temperature below the higher temperature transition in the so-called A phase of the liquid, and even more rapidly in the B phase below the second transition (*Phys. Rev. Lett.*, **30**, 962; 1973). This result strongly suggested the onset of superfluidity but the evidence was not conclusive in that the experiment did not demonstrate unambiguously the presence of any fluid with zero viscosity.

Fourth sound is a phenomenon well known in the case of liquid ^4He , which can be regarded as an homogeneous mixture of normal and superfluid components; it is a wave motion which can occur when the liquid is absorbed into a tightly packed powder. In these conditions the normal fluid component, which has a finite viscosity, is effectively immobilised but the superfluid component, with zero viscosity, is still entirely free to move. The pressure wave which can thus be transmitted through superfluid in the interstices of a tightly packed powder is known as fourth sound; and the densities of the normal fluid ρ_n and of the superfluid ρ_s can be deduced from measurements of its velocity. This wave mode can exist only if some superfluid is present, so it was natural to search for a possible fourth sound mode in each of the new phases of liquid ^3He .

The experimental cell used by the San Diego group was constructed from an epoxy resin and was tightly packed with finely ground crystals of the paramagnetic salt cerium magnesium nitrate (CMN). Pressure transducers were positioned at either end of the cell so that fourth sound, if it existed, could be both excited and detected. The function of the CMN was threefold: its adiabatic demagnetisation enabled the liquid ^3He trapped in the interstices to be refrigerated to the required temperature; it acted as the superleak in which the fourth sound could be excited; and the temperature could be deduced from measurements of its paramagnetic susceptibility. In the event it was found that fourth sound could indeed be propagated, not just in one, but in both of the new phases, proving beyond doubt that both are superfluids.

The velocity measurements were used to derive values of ρ_s , which turned out to be surprisingly low: much lower, in fact, than may be deduced from the Helsinki viscosity experiment. The reasons for this apparent inconsistency are not yet clear. The San Diego group admit, however, that their values of ρ_s may perhaps be strictly relevant only to liquid trapped in fine pores, since it is known that for ^4He under similar conditions ρ_s is somewhat smaller than in the bulk liquid. Be this as it

may, the group's experiment has now confirmed what many physicists had come to believe would probably turn out to be the case: that, with the discovery of the new phases of ^3He , the number of known superfluids in nature has been doubled.

Resolving conflicts by time sharing

from our *Animal Behaviour Correspondent*

MUCH is now understood about the control of drinking in thirsty animals and feeding in hungry animals, but relatively little attempt has been made to understand how animals behave if they are made both hungry and thirsty and given access to both food and water. Problems of such motivational 'conflicts' are of great interest in finding out how behaviour in general is organised as most animals are probably in some form of conflict for much of their lives; for example, whether to attack a rival or flee, to feed or incubate eggs. McFarland and Lloyd (*Q. J. exp. Psychol.*, **25**, 48-61; 1973) now suggest that at least in the case of feeding-drinking conflicts some animals may resolve their conflicts by operating in a manner analogous to 'time of sharing' in computers.

It had previously been found (McFarland, *Rev. Comportement Anim.*, **4**, 64-73; 1970) that in doves, the normal course of feeding or drinking is characterised by pauses during which other types of behaviour occur. For example, a hungry dove would pause at various times during feeding and if water were present, it would drink during these pauses. Interestingly, the times when the pauses in feeding occurred were not affected by either the presence of external drinking stimuli or, within limits, on how thirsty the doves were. On this basis, the drinking was said to occur by 'disinhibition': it was allowed to occur during preprogrammed breaks in the dominant behaviour of feeding.

McFarland and Lloyd define a dominant behaviour as one which is always resumed following an interruption and a subdominant behaviour as one which is resumed only if the duration of the interruption is less than that of the preprogrammed break in an alternative (dominant) behaviour. Primarily hungry animals interrupted during feeding return to feeding, and primarily thirsty animals interrupted during drinking return to drinking, so that by suitable manipulation of food and water deprivation schedules, either feeding or drinking could be made to be the dominant motivation. Their new evidence suggests that not only does the dominant system determine when subdominant behaviours occur, it also determines how long the

behaviour continues. They found that when a primarily hungry animal is interrupted while drinking or a primarily thirsty animal while feeding, the same behaviour is resumed after a short interruption, but changes to the alternative behaviour after a long interruption. In other words, if a subdominant behaviour is interrupted for a period which is longer than the pre-programmed break in the dominant behaviour, when the interruption is over it will be time for the animal to return to the dominant behaviour. An interruption which does not last longer than the allowable break in dominant behaviour will be followed by resumption of subdominant behaviour.

McFarland and Lloyd argue that when, as in the present case, the occurrence of an activity is determined by another motivational system both in terms of frequency and duration, then this should be called 'time sharing', by analogy with similar systems used on computers to overcome a similar problem—namely, to deal efficiently with simultaneous demands from several sources on limited parts of the machine.

Solvent reorganisation around a 'giant dipole'

from our *Chemical Physics Correspondent*

IT is difficult to find a new corner of science to develop these days, even a small corner can be elusive. This is, however, what Struve, Rentzepis and Jortner seem to have found in their paper on the kinetics of solvation (*J. chem. Phys.*, **59**, 5014; 1973). The thermodynamics of solvation of ions and molecules is a well studied subject but for kinetic information one must find a non-equilibrium, non-solvated species and then follow the development of solvation in the next few nanoseconds or less.

Jortner and his colleagues have solved this problem by studying the process after electronic excitation in *p*-dimethylaminobenzonitrile. In its ground state such a molecule is only weakly solvated, but its second singlet excited state corresponds to a quinoid formula (see figure) with its very large charge separation and a dipole moment of $77 \times 10^{-30} \text{ C m}$ (23 debye). Each end of the molecule will be heavily solvated, at least in polar solvents whose molecules will align themselves around the separated charges. At the instant of electronic excitation the molecule finds itself essentially unsolvated and it is the rate of subsequent solvation which

is of interest. The production of the species with non-equilibrium solvation is just the problem of exciting molecules to the quinoid state and this is accomplished with a laser flash at $37,600\text{ cm}^{-1}$ (265 nm) obtained as the fourth harmonic of a Nd^{3+} glass laser of duration about 5 ps.

The second half of the problem is to determine whether or not, at a subsequent moment of time, the quinoid state is yet solvated. This is answered by measuring the emission spectrum. If the solvation remains weak, as it will be in non-polar solvents such as methyl cyclohexane, the excited molecule loses its energy, first, by radiationless conversion to the lower excited singlet state and finally by fluorescence from this state at $28,600\text{ cm}^{-1}$ (350 nm). This process requires 20 ps and the fluorescence was detected photographically at the appropriate spectroscopic position. If the solvent consists of polar molecules, such as ethyl alcohol, the quinoid excited state is stabilised by solvation and is detectable as a new fluorescence emitter at $21,300\text{ cm}^{-1}$ (470 nm). Such fluorescence requires 50 ps to build up to maximum intensity and it is concluded that this delay corresponds to the time required for the polar solvent molecules to orient themselves around the giant dipole excited molecule. This seems a reasonable order of magnitude but the first experiments are not very precise; however, the experimental difficulties with delay paths, light shutters and so on are considerable. After all, in 50 ps light travels less than 2 cm.

New interpretation of Keweenawan rift

from our Geomagnetism Correspondent

THE 'midcontinent gravity high' of central North America is a linear belt of positive Bouguer anomalies which stretches about 1,300 km in a north-east-south-west direction from Lake Superior to Kansas. In numerical terms, the positive anomalies reach values as high as +60 mgal and for much of their length are flanked by parallel gravity lows reaching -100 mgal. According to Chase and Gilmer (*Earth Planet. Sci. Lett.*, **21**, 70; 1973), however, the shape of the belt may be more significant than the absolute values of gravity. The boundary between the highs and lows is sharply defined by very steep gravity gradients; and when the midcontinent gravity high is mapped by this boundary, it is seen to comprise several long linear segments offset from each other in a way reminiscent of the transform faults along oceanic ridges.

For this and other reasons Chase and Gilmer propose that the rocks produc-

ing the positive gravity anomalies may have resulted from plate tectonic processes which occurred during the Precambrian. That the rocks associated with the anomalies were formed during an episode of continental rifting is not, of course, a new idea in itself. In the Lake Superior region, for example, the positive anomalies lie over uplifted basaltic flows and intrusive gabbros of Keweenawan age, and the gravity lows are found over flanking basins containing younger Keweenawan sediments. The petrology and structure of the volcanics suggest that these rocks were formed during rifting of the Precambrian shield—an emplacement which zircon U-Pb ages show occurred over a short period between 1,140 and 1,120 million years ago. Moreover, evidence from gravity studies, magnetic anomaly data and boreholes indicates that the mid-continent gravity high and rifting are closely associated right through to Kansas.

But what Chase and Gilmer are suggesting is that the acknowledged rifting is the product of the sort of plate tectonic processes known to be occurring today—in other words, that the Keweenawan rift system is the result of the interaction of lithospheric plates during the late Precambrian. According to this view the offsets between the positive anomaly segments would correspond to transform faults and the segments themselves would correspond to oceanic spreading centres. The implication of this would be that the continental regions or blocks on either side of the rift would have acted as rigid plates during the rifting; and this in turn would place constraints on the geometry of the rift. Thus, assuming that these supposedly rigid plates have not been deformed subsequently, the present geometry of the rift should offer a test of the proposed rigidity.

The particular criteria to be applied in such a test are, first, that the supposed transform faults should lie along small circles about the same pole of relative rotation and, second, that the amount of rifting should increase with the sine of the angular distance from this pole. Using five supposed transform faults and the widths of the gravity high measured at eleven points, Chase and Gilmer show that a single pole of rotation may be defined to a remarkable degree of accuracy. The pole itself lies in northern New Mexico at 36°N , 107°W , the total rotation between the block to the north of the gravity high (called the Minnesota plate) and the block to the south (the Wisconsin plate) being 2.6° . At the 95% level the semi-major and semi-minor axes of the pole's oval of confidence are only 3.6° and 1.2° , respectively, and the limits on the rotation are $\pm 0.7^\circ$. The geometrical proper-

ties of the gravity high are thus indeed in close agreement with those to be expected from a plate tectonic model involving interacting rigid plates (apart from in the western Lake Superior region where matters are complicated by the presence of the mafic intrusions of the Duluth complex).

This discovery suggests, in turn, the need for a re-examination of the basic structure of the Keweenawan rift. Previous models of the structure have envisaged a basin 7–15 km deep, filled with dense Keweenawan lavas (supposedly causing the gravity high) and largely underlain by older continental crust. According to this view, the crustal separation would be represented by basaltic feeder dykes beneath the basin, and these would not be clearly defined by the observed gravity. The crustal separation involved in the hidden rifting would thus be difficult, if not impossible, to measure. This is why Chase and Gilmer used the width of the gravity high to represent the degree of rifting, realising that the two were not necessarily equal but assuming that the width of the lava-filled basin would at least be roughly proportional to the lesser width of the rifts hidden below.

But the fact that the width of the gravity high itself is in very close agreement with a plate tectonic geometry implies that this assumption is unnecessary and that the width of the gravity high is actually the width of the hidden rift. Chase and Gilmer thus go on to suggest that the lava basin did not form on a previously existing continental crust which had sunk but instead filled (and fills) the gap between the parted edges of continental plates. In this case it is no longer a matter, as previously thought, of having a relatively minor rift through which lava vented to give a lava basin controlled in width by the previous geology of the region. Instead, the Keweenawan is a major rift which ranges in width from more than 40 km at the southern end in Kansas to more than 85 km in central Lake Superior. A single gravity model is then sufficient to show that such a major rift is as consistent as the previously assumed structure with the observed gravity high.

Finally, from this particular example Chase and Gilmer go on to generalise in terms of an "evolutionary sequence" for continental rifting. They suggest that the initial stages of rifting may resemble the Rhinegraben or Baikal rift, that the next development may be similar to the East African Rift valleys, and that the Keweenawan rift type (the northern Red Sea being another and active example) represents the third stage. The final form would then be the familiar generation of new lithosphere at oceanic ridges as exemplified by today's southern Red Sea and the mid-Atlantic ridge.

Whys and wherefores of cosmic rays

How are cosmic-ray particles produced, and do some of them come from outside our Galaxy? These were the questions implicitly under discussion at a meeting held at the Royal Society on February 20 and 21.

On the second afternoon, T. Gold (Cornell University), V. L. Ginzburg (Lebedev Physical Institute, Moscow) and G. R. Burbidge (University of California, La Jolla) made their own distinctive contributions to the meeting. Gold put forward the case that pulsars could contribute at least electrons, protons and nuclei of mass around that of iron to the cosmic-ray beam. The cosmic radiation requires sources producing about 10^{34} J s⁻¹ and the average rate of production of energy by pulsars over a galactic lifetime of 10^{10} yr is reckoned to be 10^{36} J s⁻¹, so energetically the argument holds good. Gold suggested that the early and as yet undetected phases of pulsar evolution might well be instrumental in the formation of other parts of the cosmic-ray flux. He pointed out that there is already evidence from the distribution of pulsar periods, both by number and galactic latitude, that there is more than one way in which a pulsar can be created. The number distribution shows a marked bifurcation at pulsar periods of about 1 s, and Gold said that the probability of such a 'cut' in a single modal distribution is about 7%. The fact that pulsars with periods greater than 1 s are much less concentrated in the galactic plane than the others is added evidence of distinct forms of pulsar evolution.

A. W. Wolfendale (University of Durham) said earlier in the meeting that there is evidence of an upward bump in the differential energy spectrum of primary cosmic rays at energies of about 10^{15} eV, and this fitted nicely with Gold's contention that the energy spectrum of cosmic rays from pulsars should be fairly flat, with a cutoff at about that energy.

Ginzburg, whose paper was read in his absence, seems as convinced as he ever was that cosmic rays from outside the Galaxy are unlikely to contribute to the flux inside. He pointed out that if the intergalactic gas density were at the high end of the accepted range, 10^{-7} to 10^{-5} atoms cm⁻³, this would rule out some extragalactic models straight away. On the experimental side, he described several experiments which could have a crucial bearing on the problem. First, the measurement of the abundance of ¹⁰Be (half life 1.6×10^6 yr) would help differentiate between different galactic models. A complete lack of ¹⁰Be—indicating that it had all decayed—would

confirm that the halo of the Galaxy is involved in cosmic-ray propagation. Complete survival, on the other hand, would not necessarily rule out models involving the galactic disk as well as the halo. He described the measurement of the isotopic composition of cosmic rays as "on the horizon". Other experiments put forward by Ginzburg included measuring the energy spectrum of relativistic positrons, essentially to find a 'characteristic time' for cosmic rays in the Galaxy and monitoring the γ -ray flux from the galactic centre and from the Magellanic Clouds. The latter would require γ -ray detectors some 300 times more sensitive than those at present available but would place an upper limit on the input of cosmic rays from outside the Galaxy.

Following Ginzburg's advocacy of galactic models, Burbidge put forward the case for thinking that some, though not all, cosmic rays found in the Galaxy

are produced outside its confines. What of the energy implications? Burbidge recalled that filling the whole Universe with cosmic rays at the density found near the Earth (10^{-5} J cm⁻³) would require every galaxy to produce 10^{56} J in a lifetime of 10^{10} yr—1% of its rest mass, for some people a worryingly high figure. If, however, calculations are based on the assumption that only galactic clusters and superclusters (1% of the volume of the Universe) are filled with cosmic rays then only 10^{-4} of the rest mass is involved.

Arguing against the objection that extragalactic cosmic rays could not get into the Galaxy, Burbidge said that particles do diffuse into the outer parts of radio galaxies such as Cen A, so that it is difficult to see how particles will fail to get to the Earth. Burbidge appealed to "nature and more theoretical studies", which have up to now tended to be confined to galactic models.

Earthquake history

SEISMOLOGISTS and others interested in earthquake phenomena will probably already know of the two volume *Earthquake History of the United States*, originally published in 1928 and since updated several times. The latest revision brings the data together in one volume, published by the US Department of Commerce (National Oceanic and Atmospheric Administration, 1973).

The data now include earthquakes from the mid-seventeenth century (for the eastern states at least) up to 1970; as well as the catalogue of dates, intensities and places, earthquakes are given short 'eye witness' descriptions as their intensity and destructiveness justify, and maps indicate the 'seismic risk' in different parts of the contiguous United States. Anybody interested in older events (outside of the United States, of course) is referred to Milne's *A Catalogue of Destructive Earthquakes AD7 to AD 1899* (Br. Ass. Advmt. Sci., 649; 1911).

Reality of bubble nuclei

from our Nuclear Theory Correspondent

MANY studies of nuclei by electron and nucleon scattering have shown that some are spherical whereas others are more or less strongly deformed into spheroidal or ellipsoidal shapes. Studies of their excited states show that the deformed nuclei have characteristic rotational spectra but that the spherical nuclei can often be excited into a series of vibrational modes.

Wheeler pointed out long ago that these are not the only conceivable nuclear shapes. One can imagine not only wobbly drops of various shapes but more exotic configurations like bubbles and toroids. Is it possible, for example, to form a bubble of nuclear matter and if so would it be stable?

It is plainly possible to imagine a nucleus from which all the nucleons in the lowest *1s* state have been suddenly removed by a direct interaction, leaving the other nucleons undisturbed. This would be a highly excited nucleus but it might live long enough to qualify as a bubble nucleus. It is also conceivable that bubble nuclei are sometimes formed in the turbulent nuclear motions resulting from very energetic collisions of heavy ions. These bubble nuclei are likely to be highly excited but it is also possible that bubble configurations are found at low excitations or even in the ground state.

Whereas heavy nuclei can usefully be thought of for some purposes as a drop of fluid of almost uniform density, light nuclei have density distributions that can be interpreted as α -like clusters in regular array. Thus ^{12}C has a density distribution similar to that of three α s at the vertices of an equilateral triangle and ^{16}O as four at the vertices of a tetrahedron. Such nuclei may have a low central density and may be classed as bubble nuclei.

Calculations of the stability of bubble nuclei were made by Siemens and Bethe (*Phys. Rev. Lett.*, **18**, 704; 1967) using the semi-empirical mass formula and they found that some large spherical bubble nuclei may be stable against symmetry-preserving breathing expansions and contractions, but they did not investigate their stability against other distortions.

The stability of bubble-shaped nuclei against symmetry-preserving breathing deformations has also been investigated by Krishnan and Pu (*Phys. Lett.*, **47B**, 225; 1973) using the energy density formalism. They find that bubble nuclei are stable only for very large mass numbers ($A \simeq 700$), far beyond the region known at present. Lighter nuclei do not have stable bubbles.

A series of calculations using the liquid

drop model shows that bubble nuclei are unstable (Wong, *Ann. Phys.*, **77**, 279; 1973) and this confirms other calculations that do not take the shell structure of nuclei into account. If, however, the shell structure is included, some bubble nuclei with a low density of single-particle states near the Fermi surface are found to be stable. These calculations are made by assuming that the nuclear potential follows the density distribution; the energies of the single-particle states can then be found by standard procedures. The reduced potential near the centre of a bubble nucleus raises the energies of those single-particle states whose wave functions overlap with this region, and these are states of low angular momentum. Thus in a bubble configuration the energies of states of low angular momentum are raised relative to those of states with high angular momentum and this gives a new series of magic nucleon numbers for pronounced bubble configurations.

In this way Wong (*Phys. Lett.*, **41B**, 451; 1972) found the new magic numbers 18, 34, 50, 70, 80, 104, 120... at various deformations. Use of the Strutinsky method to evaluate the shell corrections then indicates ^{36}Ar , ^{84}Se , ^{138}Ce and ^{200}Hg as possible bubble nuclei in their ground states.

More detailed calculations may be made with the Hartree-Fock theory using a realistic effective nucleon interaction and some results of Curry and Sprung (*Nucl. Phys.*, **A216**, 125; 1973) for ^{36}Ar are shown in Fig. 1. Also shown is the corresponding distribution for ^{40}Ca less that of an α particle. Allowing for

Fig. 1 Density distribution of ^{36}Ar (—) compared with that of ^{40}Ca (— • —) and the density difference of ^{40}Ca and an α particle (---) obtained by Hartree-Fock calculations. The central bubble is well marked, and is identified as an α hole (Curry and Sprung).

Fig. 2 Density distribution of ^{68}Se showing the region of minimum density centred on a spherical shell of radius about 1.5 fm (Davies, Krieger and Wong).

a slight inward relaxation due to self-consistency effects the two distributions correspond very well, suggesting that ^{36}Ar has a bubble configuration corresponding to ^{40}Ca with an α particle removed from its centre. These nucleons in the α particle are not, however, in *s* states; removal of *s*-state nucleons would give ^{36}Ar in a highly excited state and a density distribution quite different from that shown.

Further calculations for a series of possible bubble nuclei have been made by Davies, Krieger and Wong (*Nucl. Phys.*, **A216**, 250; 1973) and they confirm the bubble nature of a low energy configuration of ^{36}Ar and in addition find marked bubble effects in ^{200}Hg and ^{116}Ce and ^{138}Ce . A different type of bubble is found in ^{68}Se ; the region of lower density is centred on a spherical shell of radius about 1.5 fm instead of the origin (see Fig. 2).

Detailed examination of the results of these calculations shows that in these nuclei the bubble configurations are preferred because they reduce the density of single-particle states in the region of the Fermi surface. The expected raising of states of low angular momentum relative to those of high angular momentum is indeed found in some bubble nuclei. With the same model, the strength of the spin-orbit potential of the Thomas form (proportional to the radial derivative of the density distribution) depends on the relative amplitudes for finding the nucleon at the surface or near the centre of the nucleus. This implies that for bubble nuclei the spin-orbit doublets may be inverted and the likelihood of this is greater for smaller values of orbital angular momentum. This effect is also observed in some nuclei.

These investigations show that the usual picture of nuclei having an almost uniform central density is sometimes far from the truth. There are several nuclei that show pronounced minima or bubbles in their centres and others have even more complicated departures from uniform density.

Evidence for a ~ 4.5 aeon age of plagioclase clasts in a lunar highland breccia

E. K. Jessberger, J. C. Huneke, & G. J. Wasserburg

The Lunatic Asylum of the Charles Arms Laboratory, Division of Geological and Planetary Sciences, California Institute of Technology, Pasadena, California 91109

Argon from neutron-irradiated mineral separates and whole rock samples of a metamorphosed breccia (65015) from Apollo 16 has been analysed with a large number of gas extraction steps in order to obtain a high resolution in the apparent ages and to identify the gas released from different sources. The results on plagioclase show a ^{40}Ar - ^{39}Ar plateau age of 3.98×10^9 yr, which we attribute to the time of metamorphism, and an age of $\sim 4.5 \times 10^9$ yr in the high temperature fraction. Correlation of the release pattern with ^{37}Ar instead of ^{39}Ar permits the association of the $\sim 4.5 \times 10^9$ yr age with relict plagioclase which were demonstrated in previous petrographic and Rb-Sr studies as being unequilibrated. This result suggests that it is possible to identify lithic components which represent the early lunar crust.

THIS investigation attempts to decipher the premetamorphic age of the protolith of a recrystallised breccia from Apollo 16 using the ^{40}Ar - ^{39}Ar technique. Petrographic studies have revealed in some lunar breccias, clasts which have not been brought into chemical equilibrium with the recrystallized groundmass¹. Detailed Rb-Sr studies have shown that some plagioclase clasts were not isotopically equilibrated with the matrix and consequently show isotopic evidence of a pre-metamorphic history^{2,3}. The study of such unequilibrated rocks is of major importance in penetrating the time barrier at $\sim 4.0 \times 10^9$ yr, reflecting the terminal lunar cataclysm³⁻⁶. Such results are directly applicable to the characterization of the early lunar crust and the time scale for its evolution.

Rock 65015 was known to contain Sr isotopic relicts in plagioclase mineral separates⁴ and was therefore selected for a comprehensive study with the ^{40}Ar - ^{39}Ar technique⁷. An optimal experiment would be an analysis of macroscopically recognisable plagioclase clasts which were known to be almost totally unequilibrated. Such a sample of 0.5 mg weight has provided the nearest 65015 data point to the primitive Sr isotopic composition of BABI (see Fig. 1 of Tera *et al.*⁴). A similar ^{40}Ar - ^{39}Ar analysis unfortunately requires much more material than is currently available. As a compromise, a mineral separate was chosen which was relatively large in size (47 mg) but which was still known to be distinctly off the internal Rb/Sr isochron by a small amount. This sample (plag B) may be seen in fig. 4 of Papanastassiou and Wasserburg² and fig. 1 of Tera, *et al.*⁴ Although it may superficially appear that this sample lies on the internal isochron, it must be recognised that the analytical errors are the size of the central dots. Further, the five different plagioclase separates lie precisely on a straight line which is quite different from the internal isochron, and the position of plag B along this line indicates that about 14% of plag B is composed of unequilibrated clasts as distinct from groundmass plagioclase. This was supported by inspection of the mineral separate B, which showed a higher ratio of large ($\sim 100 \mu\text{m}$) plagioclase cleavages to finer grained groundmass plagioclase

than found in another plagioclase separate, C, which is also closer to the internal isochron. Plag C is itself off the isochron by several times the possible errors, which originally led to the search for the effects in B and subsequently in the more extreme examples of non-equilibration as found in the macroscopically identifiable clasts in the uncrushed rock.

Because of complexities in both the technique (compare ref. 6) and in the breccia itself, Ar analyses were made on a whole sample and several mineral separates of 65015 using a large number of incremental heating steps in order to provide a high resolution in variations of $^{40}\text{Ar}/^{39}\text{Ar}$. It was anticipated that such high resolution measurements, together with other isotopic and petrographic observations, would allow an isolation of the appropriate parts of the 'age spectra' associated with relict retentive phases. To obtain a sharper distinction between the Ar released at low and high temperatures, presumably reflecting the outgassing from lattice sites with different retentivities, we carried out 30-50 degassing steps between $\sim 300^\circ\text{C}$ and $1,500^\circ\text{C}$ on each sample, some of which were repeated extractions at the same temperature. All samples were part of the same neutron irradiation, which minimised comparative errors. The amounts of ^{40}Ar from the radioactive decay of ^{40}K and the amounts of ^{39}Ar produced by neutron capture on ^{39}K were determined after appropriate corrections. (Ar data were corrected sequentially for: spectrometer discrimination, decay of ^{37}Ar ($\lambda_{37} = 0.01975 \text{ d}^{-1}$) and ^{39}Ar ($\lambda_{39} = 7.2 \times 10^{-6} \text{ d}^{-1}$) before analysis; Ar interferences from neutrons on Ca and K; normalisation to standard neutron fluence; subtraction of procedural blank with assumed air composition in units of $10^{-9} \text{ cm}^3 \text{ STP } ^{40}\text{Ar}$ of $(1.5 \pm 0.5) - (2.0 \pm 0.7)$ at $<1250^\circ\text{C}$, (3 ± 1.2) at 1300°C , (7 ± 3) at $1,400^\circ\text{C}$, (17 ± 8) at $1,500^\circ\text{C}$. We used: $(^{36}\text{Ar}/^{37}\text{Ar})_{\text{ca}} = 0.000305$, $(^{39}\text{Ar}/^{37}\text{Ar})_{\text{ca}} = 0.000732$, $(^{38}\text{Ar}/^{39}\text{Ar})_{\text{K}} = 0.01$, $(^{40}\text{Ar}/^{39}\text{Ar})_{\text{K}} = 0.01$.) The apparent ages were calculated from the $^{40}\text{Ar}/^{39}\text{Ar}$ ratios for each temperature release and are shown in Fig. 1A for the whole rock and two mineral separates. (Conversion factors for LAV3 irradiation: $C_{39}(\text{K}) = 8.02 \times 10^{-4} \text{ cm}^3 \text{ STP } ^{39}\text{Ar}/\text{gK}$, $\text{K}/\text{Ca} = (0.54 \pm 0.02) ^{39}\text{Ar}/^{37}\text{Ar}$. Constants in age calculations: $\lambda_{39} = 4.27 \times 10^{-10} \text{ yr}^{-1}$, $\lambda_{40} = 0.585 \times 10^{-10} \text{ yr}^{-1}$, $^{40}\text{K}/\text{K} = 1.19 \times 10^{-4}$.) The age scale is enlarged to make the fine structure visible.

The apparent ages of all samples, including two which are not illustrated, increase very rapidly to a local maximum at $\sim 600^\circ\text{C}$, followed by a decrease of $(0.05-0.1) \times 10^9$ yr. The apparent ages of the plagioclase and whole rock recover above about 840°C , whereas those of the pyroxene remain almost constant up to 900°C . A normal experiment with less resolution would not show any of this fine structure, but would give very well defined plateaux of $(3.90-4.05) \times 10^9$ yr for all samples between $500-900^\circ\text{C}$. Above 900°C , the ages of both pyroxene and whole rock decrease by $\sim 0.8 \times 10^9$ yr and $\sim 0.3 \times 10^9$ yr, respectively, whereas plagioclase exhibits a rapid increase in apparent age. The highest age of 4.5×10^9 yr is approached in a regular sequence of precise data which, except for the very last point, are not affected by blank corrections (Fig. 1B). Because the total rock is a polymineralic aggregate, its complex behaviour is not un-

FIG. 1 Differential ^{40}Ar release (A) and apparent ages (B) against extraction temperature for: a, total rock sample (64 mg); b, plagioclase B (47 mg); c, pyroxene (57 mg) separates of Apollo 16 breccia 65015; d, blank. A, The amounts of ^{40}Ar released in multiple extractions at the same temperature have been added. Vertical bars mark the temperature where $\sim 50\%$ of the total ^{40}Ar has been degassed and illustrate that the low temperature release of all samples is dominated by a high K phase. In the plagioclase curve at $\sim 1,000^\circ\text{C}$ there is a hint of a structure possibly due to the release from a high temperature 'phase'. The average blank amounts, determined from 35 procedural blank runs with maximum variations of 50% from the given curve, affect only the last extraction of each sample, but clearly not the $1,290^\circ\text{C}$ plagioclase datum. B, To separate visually the apparent age points from multiple extraction steps at constant temperature T , the age of the n th step is plotted at $(T + 5n)^\circ\text{C}$ on an expanded age scale covering the significant range. The low temperature apparent age patterns are characterised by a similar behaviour for all samples, which we attribute again to an ubiquitous high K and relatively unretentive mineral phase. Above $\sim 900^\circ\text{C}$ pyroxene shows its characteristic decrease, which is not understood. Plagioclase, on the other hand, after a well documented plateau ($865\text{--}1,000^\circ\text{C}$) increases rapidly to 4.46×10^9 yr at $1,290^\circ\text{C}$. The whole rock age pattern is a complex synthesis of all phases.

expected at this resolution. The high temperature decrease in the age of the whole rock sample can be attributed to the inclusion of pyroxene, for which the decrease at high temperatures is here again established as characteristic (see ref. 8), although it is not yet understood. The maximum ages at 600°C differ by up to 0.05×10^9 yr, but the similarity in the low temperature behaviour of all samples suggests a source for this characteristic pattern in a ubiquitous accessory phase which is not readily removed by mineral separation techniques on such fine grained material. Albee *et al.*¹ have noted that 90% of the potassium in 65015 resides in non-stoichiometric, irregularly dispersed, very fine patches, which appear to be devitrified glass (quintessence). This phase contributes a large fraction of the total ^{40}Ar released at low temperatures (Fig. 1B), as demonstrated by the fact that at low temperatures K/Ca is 10–100 times larger than at high temperatures (Fig. 2C).

In summary, we conclude that by usual standards, the $^{40}\text{Ar}/^{39}\text{Ar}$ ratios in the region between 550 to 900°C define reasonable plateaux corresponding to ages between 3.90×10^9 yr and 4.05×10^9 yr. The complex age spectra, however, are apparently the result of a blend of a common K-rich phase with the major minerals plagioclase and pyroxene. It is evident from these refined age patterns that a variety of processes must be taking place during the differential thermal analyses. The causes for the complex age spectra are not well established. A reasonable mechanism to explain the characteristic age peak at $\sim 600^\circ\text{C}$ is redistribution of ^{39}Ar because of recoil from fine grained quintessence. Typically, the low initial ages would be interpreted as a result of ^{40}Ar loss on the lunar surface. Because of the low temperature fine structure, and the possibility of ^{39}Ar redistribution, the exact extent of any ^{40}Ar loss on the lunar surface is uncertain.

We will now focus on the plagioclase results and the study of Ar released from plagioclase in the dominating presence of Ar released from other phases. It is our purpose to identify the plagioclase ages and separate them from the ages of high K impurities. Traditionally, the apparent ^{40}Ar – ^{39}Ar ages are plotted against the cumulative fractional ^{39}Ar release (Fig. 2A). In polymineralic systems containing minerals with very different K concentrations, the age pattern in this representation may be dominated by rare high K phases, which have a preponderance of total K in the sample.

Evidence for this is seen both in the fact that the total K in plagioclase separate B inferred from total ^{39}Ar is 1,475 p.p.m., in contrast with ~ 500 p.p.m. for plagioclase in 65015 determined by electron microprobe¹, and in the fact that the dominant ^{39}Ar and ^{40}Ar release occurs at low temperatures (Figs 1A and 2A). As plagioclase B is $\sim 99\%$ pure, this would require that the additional phase which releases argon at low temperatures can only amount to about one percent of the sample weight but must have a very high K content. An admixture of only 1.5% of quintessence with 6.4% K (ref. 1), can account for two-thirds of the K in plagioclase B.

In contrast to the potassium, Ca in the plagioclase is $\sim 13\%$ as compared to only $\sim 2\%$ in quintessence¹. Therefore ^{37}Ar release from our sample is related entirely to the release from plagioclase and not the K-rich, low Ca impurities. A true plagioclase plateau should be associated with the ^{37}Ar released. Figure 2B shows the data in this representation. There is a distinct low temperature peak in the high K/Ca regime (fig. 2C) and a reasonably well defined plateau over the temperature region $865\text{--}1,000^\circ\text{C}$, containing 35% of the ^{37}Ar and corresponding to an almost constant K/Ca ratio of 0.005, which is appropriate to plagioclase. It now becomes evident that the $\sim 600^\circ\text{C}$ peak is a disturbance. Since it covers approximately the first 50% of the ^{39}Ar release (Fig. 2A), it would normally be interpreted as an intrinsic part of the plateau, but it is identified in the ^{37}Ar plot as a minor contribution from a high K phase in the age spectrum of plagioclase. In the high temperature regime, the sharp increase of the apparent age to 4.5×10^9 yr is

TABLE 1 Argon ages in breccia 65015 (inferred from plagioclase mineral separate B)

	Gas retention age ($\times 10^9$ yr)*	Exposure age (m.y.)†
865–1,000° C		
'equilibrated plagioclase'	3.98 ± 0.01	466 ± 1
1,290° C		
'unequilibrated plagioclase clasts'	4.46 ± 0.05	≥ 505

* When comparing these ages with those from other laboratories or other irradiations, an additional error of $\pm 0.04 \times 10^9$ yr from the uncertainty in C_{39} (K) has to be included.

† Calculated with production rate $P_{38} = 1.4 \times 10^{-8}$ cm³ STP $^{38}\text{Ar}/\text{g Ca my}$ and excluding an error of ± 17 m.y. from C_{37} (Ca).

more obvious and is correlated with the last 15% of the ^{37}Ar release, as compared with the last 5% of the ^{39}Ar release. It should be noted that these observations depend critically

FIG. 2 Isotopic composition of Ar from a plagioclase separate of Apollo 16 breccia 65015, against (A) fractional release of ^{39}Ar , and (B-E) fractional release of ^{37}Ar . The graph of apparent age against ^{39}Ar (A) is dominated by Ar released from K-rich, Ca-poor accessory phases. Graphs against ^{37}Ar emphasise the composition of Ar from Ca-rich plagioclase and reveal (between vertical dashed lines) a well-defined intermediate plateau at 3.98×10^9 yr (B). This is associated with the appropriate K/Ca for plagioclase (C), a constant $^{36}\text{Ar}/^{38}\text{Ar}$ (E) at a value appropriate for spallogenic Ar, and a well defined plateau in $^{36}\text{Ar}/^{37}\text{Ar}$ (D) indicating a cosmic-ray exposure age of 466 m.y., all ascribed to plagioclase degassed or recrystallised by metamorphism at 3.98×10^9 yr. The last 10% of ^{37}Ar release shows increases in apparent age associated with increases in K/Ca and $^{36}\text{Ar}/^{37}\text{Ar}$, but constant $^{36}\text{Ar}/^{38}\text{Ar}$. We attribute this to unequilibrated and incompletely degassed plagioclase clasts from the protolith of 65015 previously recognised by petrographic and Rb/Sr studies, and infer for them a formation age of $\sim 4.5 \times 10^9$ yr, and exposure to cosmic rays before 3.98×10^9 yr.

on high resolution data. If there were only ten equal steps, then the last four releases would have given an apparent age of 4.2×10^9 yr.

It is most plausible to associate the plateau of 3.98×10^9 yr on the ^{37}Ar plot with plagioclase which has completely lost ^{40}Ar in a metamorphism at that time, and to further associate the age peak at $\sim 600^\circ\text{C}$ with the crystallisation of quintessence at approximately the same time. The age of 4.5×10^9 yr obtained in the highest temperature release from the plagioclase separate is one of the most interesting and possibly most important results of the present work. It is plausible to correlate this age with the plagioclase clasts which have not been thoroughly equilibrated and outgassed during this metamorphism. It is conceivable, however, that the high age values are artefacts. As a test of this, the $^{36}\text{Ar}/^{38}\text{Ar}$ and $^{36}\text{Ar}/^{37}\text{Ar}$ ratios can be inspected for irregularities (see Figs. 2D and E). Again the ^{37}Ar plot is the most convenient representation, since Ca is the predominant target nucleus for the production of spallogenic Ar by cosmic rays. It can be seen that the $^{36}\text{Ar}/^{38}\text{Ar}$ ratio is remarkably constant at 0.62, in good agreement with typical spallation values on Ca and Fe (ref. 9). There is a hint of slight fluctuations ($\sim 6\%$) in the last 10% of the ^{37}Ar release. The $^{36}\text{Ar}/^{37}\text{Ar}$ shows a broad plateau after the first 10% and up to the last 15% of ^{37}Ar release. The pattern of $^{36}\text{Ar}/^{37}\text{Ar}$ characterises a well defined cosmic-ray irradiation age, with spallation $^{36}\text{Ar}_s$ exactly correlated with the Ca target, as measured by ^{37}Ar . The last $\sim 15\%$ of the ^{37}Ar release shows a small but distinct ($\sim 10\%$) increase in $^{36}\text{Ar}_s/^{37}\text{Ar}$ correlating with the high $^{40}\text{Ar}/^{39}\text{Ar}$ part of the age spectrum and also some variations in K/Ca. The most obvious interpretation is to consider this as reflecting a pre-irradiation of the older plagioclase clasts before the formation of the recrystallised breccia, in which case the clasts must have resided for some time in the upper few metres of the lunar surface before the last major collision causing the metamorphism. The increase in $^{36}\text{Ar}_s/^{37}\text{Ar}$ cannot be due to a marked change in chemistry (for example, Fe or Ti enrichment¹). A production of ^{38}Ar by neutron reactions on ^{37}Cl is highly improbable since $^{36}\text{Ar}/^{38}\text{Ar}$ is constant. If the $^{36}\text{Ar}_s/^{37}\text{Ar}$ increase is an artefact, it is a factor of two smaller than that manifested in the $^{40}\text{Ar}/^{39}\text{Ar}$ ratio, and a factor of $\sim 10^2$ smaller in the number of ^{40}Ar atoms as compared with the $^{36}\text{Ar}_s$. Thus we do not consider the change at high temperatures in the ratios of the spallogenic isotopes to be indicative of artefacts in $^{40}\text{Ar}/^{39}\text{Ar}$ ratios. The average K/Ca is 20% higher in the plagioclase which apparently retains Ar from dates before 3.98×10^9 yr. Observations on the cores of plagioclase clasts show that they are usually slightly lower in K than the rims and matrix plagioclase, although some do have relatively higher K contents.

The correlation of gas release from plagioclase with the ^{37}Ar release enables us to estimate that $\sim 15\%$ of plagioclase B can be related to high ages, which is in striking agreement with $\sim 14\%$ inferred from Rb/Sr studies of the same separate. This provides another very important and independent argument for the association of the $\sim 4.5 \times 10^9$ yr ages with unequilibrated plagioclase clasts. The argument is considerably strengthened by the observation of a similar $^{40}\text{Ar}/^{39}\text{Ar}$ increase to $\sim 4.1 \times 10^9$ yr in approximately the last 5% of the ^{37}Ar release from plagioclase C, which Rb/Sr studies indicate contains only $\sim 8\%$ unequilibrated clasts.

Thus, the analysis of the high resolution differential thermal release patterns of all Ar isotopes from neutron irradiated samples of the lunar rock 65015 indicates that this breccia was metamorphosed and recrystallised 3.98×10^9 yr ago, at about the time of the terminal lunar cataclysm. Part of the plagioclase shows a distinctive high temperature age maximum of 4.46×10^9 yr which is interpreted as being due to incomplete outgassing of old plagioclase clasts

during the metamorphic event. These results are in support of the reports by other workers^{6,10} on evidence for more ancient ages in some lunar samples. In the instance of 65015, the ages gain credence from corroborating petrographic and Sr isotopic studies, but the firm assignment of a precise time to some part of a ^{40}Ar - ^{39}Ar release pattern requires a complete understanding of the nature of ^{40}Ar - ^{39}Ar variations. The plagioclase clasts are tentatively considered to have original ages of formation of at least 4.46×10^9 yr and therefore provide evidence for the existence of some early Lunar crust with plagioclase of this composition formed 4.5×10^9 yr ago. There is no evidence in the data for intermediate metamorphic events. The data are consistent with a simple history of formation of some constituents of the breccia before $\sim 4.5 \times 10^9$ yr and subsequent formation of the breccia followed by severe metamorphism 3.98×10^9 ago. This is in agreement with a two stage evolution model for the lunar crust with these identical age limits established by Pb/U, Th systematics for an extensive suite of samples which includes 65015.

The high ^{40}Ar - ^{39}Ar age of part of the plagioclase is accompanied by a slightly older exposure age relative to the rest of the breccia, which is indicative of a pre-irradiation. Generalising the 65015 results, we propose that the protolith of many impact breccias includes in part material which resided for some time in the outer few meters of the lunar surface before the metamorphism which resulted from major impacts $\sim 4.0 \times 10^9$ yr ago.

Evidence for continental crust beneath the Faeroe Islands

M. H. P. Bott, J. Sunderland & P. J. Smith

U. Casten & S. Saxov

Laboratory for Geophysics, University of Aarhus

Recent crustal seismic refraction experiments in the North Atlantic indicate that the Faeroe Islands are underlain by continental crust. This suggests that the whole Rockall-Faeroe Plateau may be a microcontinent which formed during the early evolution of the North Atlantic.

THE Faeroe Islands lie at the north-eastern end of a region of shallow banks in the North Atlantic known as the Rockall-Faeroe Plateau (Fig. 1), which is separated from the United Kingdom continental shelf by the Rockall Trough and Shetland-Faeroe Channel. It has recently been demonstrated that Rockall Plateau at the south-western end of this region is underlain by ancient continental crust¹⁻³. The Faeroe Islands also lie at the south-eastern end of another shallow feature known as the Iceland-Faeroe Ridge, but this is fundamentally different from Rockall Plateau in that it is underlain by anomalous Icelandic-type oceanic crust formed by differentiation from the mantle over the last 60 m.y., during the evolution of the North Atlantic by seafloor spreading^{4,5}. The

Faeroe Islands themselves are formed by a thick pile of nearly flat-lying lavas of early Tertiary age whose base is not seen⁶; the exposed lavas are radiometrically dated⁷ at 50 to 60 m.y. which makes them contemporaneous with the early Tertiary volcanic activity of north Britain and Greenland. The nature of the crust beneath the Faeroes is thus problematical—is it continental or anomalous oceanic? The answer is crucial to our understanding of the Tertiary development of the north-eastern North Atlantic. We give new evidence from a crustal seismic refraction experiment which indicates that the lavas of the Faeroe Islands are underlain by continental crust about 30 km thick.

Before the present work, two items of evidence indicated that the Faeroe Islands may be continental. First, Bott and Watts⁸ showed, in making a pre-Tertiary continental reconstruction of the north-eastern North Atlantic, that if Rockall Plateau is regarded as continental then the Faeroe Block must also be continental to give an acceptable fit with Greenland. Second, a steep Bouguer anomaly gradient occurs between the Iceland-Faeroe Ridge and the Faeroe Block, indicating that the mean crustal density is significantly less beneath the block than the ridge and suggesting funda-

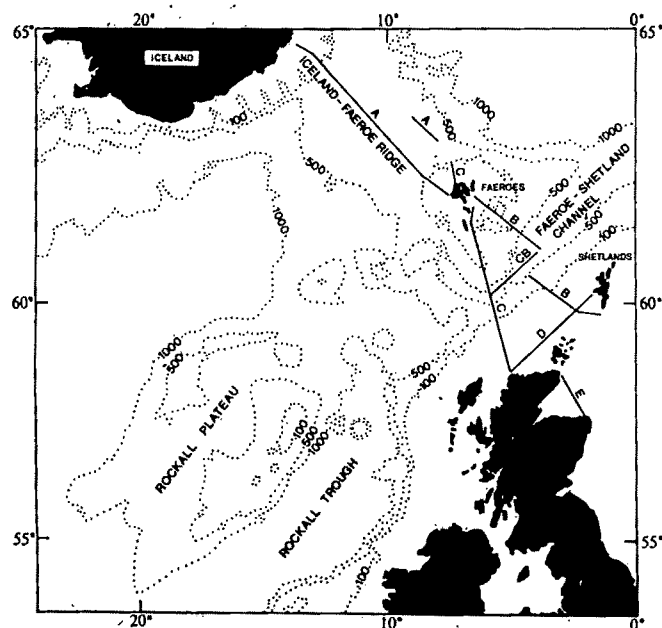

FIG. 1 Map of the region between Scotland and Iceland, showing the position of the Faeroe Islands in relation to Rockall Plateau and the Iceland-Faeroe Ridge, and the lines of shots fired during the North Atlantic Seismic Project. The following bathymetric contours are shown: 100, 500 and 1,000 fathoms.

mentally different types of crust beneath the two adjacent regions^{4,5}. Conversely, an early seismic refraction experiment made by Pálmason⁹ gave a 6.4 km s^{-1} basement beneath 2.5–4.5 km of lavas, indicating a structure similar to that beneath Iceland¹⁰. Another seismic experiment made by Casten¹¹, however, gave an unreversed basement velocity of 5.9 km s^{-1} which would be in accord with normal continental crust.

During a major seismic refraction project between Scotland and Iceland in 1972, geophex shots of 300 to 2,000 pound were fired along the lines A to E shown in Fig. 1. Recording stations were situated on Iceland, Faeroe Islands, Shetland and Orkney Islands; and the Scottish mainland. Shots were also recorded at sea by MV *Miranda* and the Russian ship *Michail Lomonosov*. Seven recording stations were placed on the Faeroe Islands, six provided by Aarhus University (in cooperation with Hamburg and Kiel Universities) and one by Durham (Fig. 2). A preliminary interpretation of that

FIG. 2 Map showing the shot positions (●) and seismic recording localities (triangles) used in the present analysis. 100 and 500 fathom bathymetric contours are shown. Shots B6, C40, C53 and C57 were misfires and are not shown.

part of the project which concerns the crustal structure of the Faeroe Block is given in this paper, using data received at four of the Faeroe stations, the ship *Miranda* and the United Kingdom Atomic Energy Authority (UKAEA) array station on the Shetland Islands (Fig. 2).

The P_g arrivals from shots on the Faeroe shelf fall into two groups as follows: (1) those from shots on the north Faeroe shelf, and (2) those from shots to the east and south of the Faeroe Islands. These two groups need to be treated separately. The records from shots on the north Faeroe shelf yield apparent velocities as follows: line A: DU4– $6.17 \pm 0.14 \text{ km s}^{-1}$, F1– $5.98 \pm 0.08 \text{ km s}^{-1}$, F2– $6.18 \pm 0.12 \text{ km s}^{-1}$, *Miranda*– $5.98 \pm 0.22 \text{ km s}^{-1}$; line C (north-west): DU4– $5.92 \pm 0.08 \text{ km s}^{-1}$. The observations at station F1 and on *Miranda* roughly reverse line A suggesting a true P_g velocity of 5.95 km s^{-1} between these stations. A time-term analysis¹² on all the north Faeroe shelf data available, including that of Pálmason⁹, yields a value of P_g velocity of $6.18 \pm 0.09 \text{ km s}^{-1}$. We have looked again at Pálmason's earlier results⁹, and we find that if first arrivals only are used then the velocity of the basement beneath his reversed line is 5.9 km s^{-1} . Thus our results suggest that the true P_g velocity in this northern region is within the range 5.9 to 6.2 km s^{-1} . This value is significantly lower than the velocity of 6.4 km s^{-1} for the lower crustal layer beneath Iceland but it is fairly typical of metamorphic basement rocks of the continental crust. The time terms for individual shots and stations in this region are of the order of 0.3 to 0.6 s, which are consistent with a varying thickness of between 2.5 and 5.0 km of lavas of average velocity 4.9 km s^{-1} overlying a basement of velocity 6.1 km s^{-1} . Alternatively a thinner lava sequence may be separated from the basement by pre-Tertiary sediments forming a low velocity layer.

Arrivals of P_g waves from shots to the south and east of the Faeroe Islands yield apparent velocities as follows: line B (shot times corrected for known sediment thicknesses): DU4– $5.28 \pm 0.02 \text{ km s}^{-1}$, F2– $6.00 \pm 0.08 \text{ km s}^{-1}$ from 0 to 50 km and $5.31 \pm 0.04 \text{ km s}^{-1}$ from 50 to 110 km; line C: DU4– $5.52 \pm 0.08 \text{ km s}^{-1}$, F2– $4.97 \pm 0.04 \text{ km s}^{-1}$, F6– $5.38 \pm 0.06 \text{ km s}^{-1}$. A time-term analysis on all the data here yields a refractor velocity of $5.53 \pm 0.08 \text{ km s}^{-1}$. The arrivals from line B recorded at station F2 (Fig. 3) are particularly significant, indicating that the 6 km s^{-1} basement beneath the northern region gives way to a lower velocity basement which occurs to the south-east of a line very approximately passing beneath shot 3 of line B in a NE-SW direction. The 5.3 to 5.5 km s^{-1} basement refractor to the south-east of this line could be interpreted as a folded series of shales, greywackes, slates and so on striking in a north-east to south-west direction. No higher velocity first arrivals attributable to P_g have been observed, implying that the 5.4 km s^{-1} layer must extend to substantial depth.

Shots on lines B and C on the Faeroes shelf beyond a distance of about 110 km give rise to the Moho head wave P_n observed at stations DU4 and F2 on the Faeroe Islands (Fig. 3). This data by itself is not adequate to determine satisfactorily the crustal structure of the Faeroe Block, but fortunately good P_n arrivals from shots on the northern and eastern parts of the Faeroe shelf were observed at the Shetland array station. We have therefore carried out a time-term analysis of P_n arrivals at stations DU4 (=B1), F2 (=C54B) and UKAEA for the following shots: line A 1–6, line B 1–16, line C 54A, 54C and 55–59. The resulting estimate of P_n is $8.24 \pm 0.35 \text{ km s}^{-1}$ and, excepting an anomalous low value of 2.83 s at shot A1, all the time-terms on the Faeroe Block lie between 3.15 and 4.00 s. The mean time-term is 3.60 s which yields a mean crustal thickness of 33 km for an average crustal velocity of 6.1 km s^{-1} , or 40 km for 6.6 km s^{-1} . The mean time term for the stations and shots in the immediate vicinity of the Faeroe Islands (that is, stations DU4 and F2, shots A1–3, C54A, C54C, C55 and C56)

FIG. 3 Reduced time-distance graph for shots B1 to B16 at station F2 on the Faeroe Islands.

is 3.45 s, yielding crustal thickness estimates of 31 km for 6.1 km s^{-1} and 38 km for an average crustal velocity of 6.6 km s^{-1} . If, on the other hand, the true P_n velocity is 8.0 km s^{-1} , then the average time terms are slightly reduced and the resulting crustal thickness estimates are about 5–10% lower than those given above.

Although the velocity of P_n is not particularly well determined, the time terms are determined with some confidence. Depending on assumptions of true P_n value and mean crustal velocity, the crustal thickness beneath the Faeroe Islands is estimated to lie between about 27 and 38 km. There is no evidence for a 6.4 to 6.8 km s^{-1} layer at fairly shallow depth, such as gives rise to clear first arrivals on Iceland and the northern part of the Iceland-Faeroe Ridge, but this does not exclude the possibility that such higher velocities occur in the lower part of the crust.

Our results show that the crust beneath the Faeroe Block differs in four important respects from the anomalous oceanic crust beneath Iceland¹⁰ and the Iceland-Faeroe Ridge⁴: (1) P_n velocities of 5.9 to 6.2 km s^{-1} and less are characteristic of the Faeroes but velocities within this range have not been observed beneath Iceland; (2) a 6.4 to 6.8

km s^{-1} layer (oceanic crustal layer 3?) is present beneath Iceland and the Ridge but has not been observed at a shallow depth beneath the Faeroes; (3) a high sub-Moho P_n velocity of 8.2 km s^{-1} is observed for the Faeroes, in contrast to the anomalously low value of 7.2 km s^{-1} beneath Iceland; (4) the Faeroes' crustal thickness of about 30 km is substantially greater than that beneath Iceland. Our results thus seem to confirm that continental crust underlies the Faeroe Islands and the adjacent shelf regions. This suggests that the Rockall-Faeroe Plateau as a whole may form a single microcontinental fragment which originated as a result of the early stages in the evolution of the north-eastern North Atlantic, with subsequent strong subsidence affecting parts of the region between Rockall Plateau and the Faeroes.

We are grateful to the Natural Environment Research Council for financial support of the UK contribution and for provision of ship time, to the Statens Naturvidenskabelige Forskningsrad for financial support of the Danish contribution, to Dr H. I. S. Thirlaway for loan of the UKAEA mobile array station placed on Shetland Isles, to Mr G. L. Wilson, Mr D. Asbery and Mrs M. E. Watson for technical assistance and to many colleagues who took part in the project.

Direct physical evidence for secondary structure in an isolated fragment of R17 bacteriophage mRNA

Jay Gralla, Joan A. Steitz & Donald M. Crothers

Departments of Chemistry and Molecular Biophysics and Biochemistry
Yale University, New Haven, Connecticut 06520

The region of R17 RNA protected from RNase digestion by coat protein assumes a stable, predictable secondary structure. It seems that this structure is recognised by the protein when functioning as a translational repressor.

NUCLEOTIDE sequence analysis of naturally occurring RNA molecules generally reveals sequences which may be arranged into plausible secondary structures. In the case of the RNA bacteriophages, specific structures have been suggested for many segments of the single-stranded genome, including the three ribosome binding sites¹, extracistronic regions at the 5' and 3' termini²⁻⁶, and the phage coat pro-

tein cistron⁷⁻⁹. Recently, Bernardi and Spahr¹⁰ characterised a 59-nucleotide fragment from R17 RNA which is specifically protected from nuclease digestion in the presence of coat protein. Thermodynamic rules for the evaluation of RNA secondary structures¹¹ predict a structure for the fragment consisting of two very stable hairpin helices (see Fig. 1). We have investigated the secondary structure of the isolated fragment by physical techniques and find close agreement between the observed properties of the RNA and those expected based on the proposed secondary structure. Magnetic resonance measurements reported in an accompanying paper give further strong support for secondary structure¹².

Our measurements differ from a conventional melting curve in that we resolve the time dependence of the melting process after a temperature perturbation. The data are obtained as oscilloscope traces^{11,13} which display both the time dependence and the total absorbance change. The latter can be plotted as a function of average cell temperature (average of initial and final values) for a constant temperature-jump size. The result (Fig. 2) is a derivative of the standard melting curve. The presence of two maxima in the derivative curves indicates that melting occurs in (at least) two steps, as would be expected for the secondary structure in Fig. 1.

TABLE 1 Stability of RNA secondary structure

	T_m in 0.05 M Na ⁺	T_m in 8 mM Mg ²⁺	T_m adjusted 1 M Na ⁺	ΔG (25° C)	ΔG (61° C)	ΔG (83° C)
Hairpin <i>b</i>	48° C	64° C	61° C	-5.0 kcalorie-mol ⁻¹	0 kcalorie-mol ⁻¹	+3.2 kcalorie-mol
Hairpin <i>a</i>	70° C	88° C	83° C	-11.4 kcalorie-mol ⁻¹	-4.5 kcalorie-mol ⁻¹	0 kcalorie-mol

The experimental T_m values were adjusted to 1 M Na⁺ by assuming an increase in T_m of 13° C for an increase by a factor of 20 in Na⁺ concentration. This increment is the average of the estimated minimum (8° C, from ref. 14) and maximum (17° C, in 8 mM Mg²⁺, Fig. 2c) variation. ΔG values refer to 1 M Na⁺.

The time resolution of the absorbance change indicates that each maximum in the differential curve corresponds to melting of a single helix, because the absorbance change separates into just two relaxation components. One of these is very fast, less than a few microseconds, and is nearly constant in amplitude between 40° C and 80° C. This is the usual behaviour for unstacking of bases in single-strand regions, and for temperature variation of the double helix absorbance^{11,13}. The other relaxation component is slower, can be described by a single exponential decay, and its amplitude peaks sharply at the maximum of the differential curve; relaxation times are shown in Fig. 3. These properties are characteristic of the melting of model double

Fig. 3 Measured terminal relaxation time (τ), plotted logarithmically versus reciprocal of final temperature. Open circles were obtained in buffer I described in Fig. 2. All relaxation could be fit to a single exponential. Closed circles were obtained in the same buffer with added coat protein as described in Fig. 2b. Only four points are shown since the relaxations were difficult to analyse quantitatively over the entire temperature range. The data could be fitted to a single terminal exponential, but an additional exponential of approximately 100 μ s was also present in the lower temperature transition.

helices^{11,13-16}. If two double helices were melting at one of the differential maxima, they would have to have identical kinetic properties and identical T_m values at two salt concentrations in order to give a single relaxation component. Such a coincidence is sufficiently unlikely that it can be discounted.

The T_m and enthalpy of melting for each of the two helices can be extracted from the differential melting curve by methods described previously^{11,13}. The results are shown in Tables 1 and 2, where the heat and thermal stabilities are compared with values expected for helices *a* and *b*, based on our published thermodynamic parameters for model helices¹¹. Agreement of observation and prediction is good if the lower temperature transition is assigned to hairpin *b*. This assignment is strongly supported by the NMR results in an accompanying paper¹².

Table 1 also includes an estimate of the free energy of forming each helix at several temperatures, calculated from the measured heat of melting and the T_m corrected to 1 M Na⁺. At 25° C, secondary structure formation is strongly favoured; we estimate that the fraction of molecules in which helix *b* is unbonded at 25° C (1 M Na⁺) is about 2×10^{-4} and even less for helix *a*. Therefore we conclude that the RNA fragment forms a stable secondary structure, and the pattern of thermal unfolding is that expected for the two hairpin helices predicted from the sequence. We find no evidence for any additional stable structure with appreciable hypochromism.

Combination of the differential melting curve with the relaxation times allows calculation of forward and reverse rate constants for each helix^{11,13,15} (Fig. 4). The observed rate of helix formation is somewhat slower than is found for some model hairpin helices^{11,14}, but not unusual when compared with values found for tRNA^{17,17a}.

Binding of coat protein

When intact R17 RNA is incubated with coat protein, the formation of a complex can be detected by sedimentation in sucrose gradients²¹. Estimates of the number of protein molecules bound per RNA range from one to six^{18,21}. Since coat protein is a known inhibitor of replicase expression, it was suggested that the bound protein interferes with translation by directly preventing the attachment of ribosomes to the beginning of the replicase gene¹⁰. We have shown that the fragment protected by coat protein (Fig. 1) assumes a stable secondary structure, and we can now ask

TABLE 2 Comparison between predicted and experimental thermodynamic parameters

	Experiment		Prediction	
	T_m	ΔH	T_m	ΔH
Hairpin <i>b</i>	61° C	-47 kcalorie	59° C	-56 kcalorie
Hairpin <i>a</i>	83° C	-70 kcalorie	80° C	-80 kcalorie

Parameters refer to 1 M Na⁺.

whether the interaction with coat protein alters its physical properties.

First, we showed that the coat protein rebinds to the isolated fragment and determined the stoichiometry of the interaction. The apparent molecular weight of the complex as a function of added coat protein was measured by sedimentation equilibrium (Fig. 5). The weight average molecular weight of the RNA reaches a plateau value after the addition of 1 mol coat protein per mol RNA. Agreement between the observed molecular weight and the actual value (both the nucleotide and amino acid sequences are known) requires that the unknown effective partial specific volume (\bar{v}) of the complex be 0.74. The end point of the binding curve clearly indicates that on the average a 1:1 complex is formed, as has been reported previously for the whole RNA containing this sequence¹⁸.

Does the presence of bound protein affect the melting of the RNA secondary structure? Temperature-jump melting curves were obtained for the RNA-protein complex (Fig. 2b). The kinetics for the terminator helix *a* are unchanged, but strikingly, the rate of melting the initiator hairpin *b* is 100 times slower in the complex (Fig. 3). Coat protein therefore must interact with hairpin *b* in a manner which slows its melting. Although the terminator hairpin kinetics are unchanged, we cannot positively exclude the possibility of its interaction with coat protein since even the bound

Fig. 4 Arrhenius plot of the temperature dependence of the RNA formation (k_1) and dissociation (k_{-1}) rate constants in buffer I. Resulting dissociation activation energies are +32 kcalorie for the lower transition and +54 kcalorie for the upper; the formation activation energy is -14 kcalorie in both cases. Rate constants were calculated as follows: the T_m and ΔH corresponding to each transition were determined¹⁸ from the peak position and width of the corrected differential melting curve (see Fig. 2), allowing calculation of the equilibrium constant K at any temperature. Knowledge of the relaxation times (Fig. 3) is then sufficient to calculate the rate constant by the equations $K = k_1/k_{-1}$ and $1/\tau = k_1 + k_{-1}$.

Fig. 5 Apparent molecular weight of the RNA-protein complex in buffer I as a function of added coat protein. Molecular weights were measured at 23° C and 266 nm in a model E analytical ultracentrifuge equipped with ultraviolet scanning optics. These were calculated in the standard manner, where M (apparent) = $(2RT/\omega^2)/(\partial \ln c/\partial x^2) = (1 - \bar{v}\rho)M$ (true), where \bar{v} is an effective partial specific volume that also accounts for polyelectrolyte effects. Each point represents a run where previously unused RNA was mixed with coat protein at the indicated relative molar concentrations. The concentration of RNA was always 0.66 μ M at 260 nm. Plots of $\log c$ against x^2 were linear within experimental error. Under the conditions used, the absorbance is predominantly that of the RNA, so M (apparent) is only slightly affected by the presence of free protein.

protein might become denatured at this higher melting temperature. The melting temperature (within experimental error) of neither hairpin is altered upon complex formation (Fig. 2b). This observation by itself could mean that the protein binds equally well to the hairpin helix *b* and the single strand, or that the free energy of binding is nearly zero at the T_m , or that an irreversible process, presumably involving protein denaturation, occurs at the T_m . We favour the last explanation because of the thermal instability of the isolated R17 coat protein.

What aspect of RNA structure is responsible for specific recognition of the fragment by R17 coat protein? We have found that (1) on the average one coat protein is bound per RNA molecule (Fig. 5); (2) the RNA is recognised while it assumes a stable secondary structure (Fig. 1); (3) the rate of melting of the helix which includes the initiator triplet is slowed in the RNA-protein complex (Fig. 3); (4) T_1 digestion of the R17 RNA-coat protein complex sometimes yields only the initiator hairpin in the protected fragment but never only the terminator hairpin (Fig. 1); (5) coat protein will not rebound the T_1 RNase-digested fragment¹⁹; (6) coat protein will specifically bind the isolated replicase initiator region¹⁹, which includes only hairpin *b* of the fragment in Fig. 1.

We conclude that coat protein recognition most likely requires some aspect of the RNA secondary structure, rather than simply a single-strand sequence. The structure which is recognised includes the ribosome binding site at the beginning of the replicase gene. Assuming that a similar structure is formed in the intact R17 RNA molecule, the direct interaction of coat protein with this region would provide a molecular explanation for the translational repression.

Are binary systems involved in supernova explosions always disrupted?

No known pulsar is a member of binary system. Does this mean, as has been suggested¹, that pulsars are the result of supernova explosions (hypothesis 1), and explosions which occurred in binary systems have in most cases disrupted the systems (hypothesis 2)? The discovery of two X-ray 'pulsars' (Cen X-3 and Her X-1) and other compact X-ray sources in binary systems seems to be an argument against hypothesis 2 if we believe that hypothesis 1 is also valid for compact X-ray sources. Here I show that hypothesis 2 is indeed untenable from the point of view of present theories of close binary evolution.

A binary system with period of several years may be close enough for the original primary to lose a considerable amount of its mass through the mass transfer in the late stage of its evolution². Van den Heuvel³ shows that 80% of the known OB spectroscopic binaries will undergo case B mass transfer (during hydrogen shell burning). Therefore it is reasonable to believe that supernova explosions in close binary systems are mostly preceded by mass transfer.

It is interesting that all known massive X-ray binaries have a common property that they consist of an OB supergiant with mass of about $30 M_{\odot}$ and a compact object with mass in the range between ~ 0.5 and $\sim 5 M_{\odot}$ (ref. 4). In five of the six known X-ray binaries the compact object has $M < 3 M_{\odot}$; only in Cyg X-1 might it be more massive. The large mass ratio of these massive X-ray binaries supports the hypothesis that the explosion is more likely to have occurred after the mass transfer. In that case the exploded star is more likely to be the less massive component⁵.

I assume that the mass of the original secondary (presently the primary) is constant during the explosion. The explosion is supposed to be spherically symmetric and to take place instantaneously. I also assume that initially the orbit is circular. Adopting these assumptions and taking the effects of the impact of the supernova shell onto the unexploded component into account in the way formulated by Colgate⁶, one can show that the condition for a binary

system to remain bound after a supernova explosion is⁷

$$\alpha + 2\beta - \gamma - 1 > 0, \quad (1)$$

where $\alpha = M_2/M_1$, $\beta = M_1'/M_1$ and γ is the ratio (gain in kinetic energy of the unexploded star due to the impact)/(initial orbital energy). M_2 is the mass of the unexploded component; M_1 and M_1' are the mass of the exploded star before and after the explosion respectively.

I assume a typical value for the velocity of matter ejected by a supernova explosion is 10^9 cm s^{-1} (ref. 8). For a given combination of values of M_2 , M_1' and the initial orbital period P , one can determine from the inequality (1) the critical value of α (α_{cr}) below or equal to which the condition (1) is unsatisfied (that is, the binary will be disrupted). I take $M_2 = 30 M_{\odot}$ and $M_1' = 1$ and $5 M_{\odot}$ re-

FIG. 1 The values of α_{cr} as a function of P for systems with final masses $30 + 1 M_{\odot}$ (—) and $30 + 5 M_{\odot}$ (---). For a given value of P the binary system will be disrupted if $\alpha < \alpha_{cr}$. The horizontal lines labelled α_{min} and α_{max} indicate respectively the lower and upper limit of the possible values of α (see text).

spectively. These values seem to be representatives for all massive X-ray binaries. The values of α_* as a function of P are given in Fig. 1.

It is likely that in massive X-ray binaries only a small fraction f of the transferred mass will escape from the system⁹. I assume that $f \lesssim 30\%$ which is consistent with the conclusions obtained from observations of evolved close binaries^{9,10}. If the explosion takes place after case B or case C mass transfer and if $f \lesssim 30\%$, the possible values of α are between ~ 1.1 and ~ 6 for $M_2 = 30 M_\odot$ (my unpublished work). From Fig. 1 one can see that all binaries with periods larger than about 5 d will remain bound after the explosion. Binaries with such periods form about 50% of the O-B5 spectroscopic binaries in Batten's Catalogue¹¹. Since, if the remnant mass is larger than $1 M_\odot$, also some binaries with a period of less than 5 d remain bound after the explosion, the probability of maintaining close binary systems (at least for close binaries with an O-B5 component) through supernova explosions should be considerably larger than 50%. Therefore the disruption of such binary systems involved in supernova explosions is more likely to be an exception rather than a rule.

Even if f is 40%, systems with $P \gtrsim 5$ d in which the remnant mass is $\gtrsim 2 M_\odot$ will remain bound. My results do not depend critically on the exact choice of a limit for f . So it seems necessary to seek another explanation for the non-existence of radio pulsars in binary systems. The absorption and smearing out of the radio pulses by the gas flows in the system might be such an alternative explanation.

I thank Professor E. P. J. van den Heuvel for advice and Dr H. R. E. Tjin A Dje for discussion. A scholarship from the Dutch Ministry of Education and Science is acknowledged.

Internal rotation of the Sun and the solar neutrino flux

THE low upper limit of 1 SNU (10^{-26} captures per ^{37}Cl atom s^{-1}) on the observed neutrino flux from the Sun obtained by Davis¹ has proved an embarrassment to stellar physicists, and in spite of considerable intellectual gymnastics the standard solar models predict at least 6 SNU (ref. 2). The essential difficulty has been to produce a model with a low enough central temperature that can still produce the observed luminosity of the Sun with an age of 4.7×10^9 yr.

Arguments for a rapid central rotation, causing a low neutrino flux, are elaborated below.

The equations determining the structure of a non-uniformly rotating star can be averaged over spheres and, provided the rotation is not too large, approximate to^{3,4}

$$\frac{1}{\rho} \frac{dP}{dr} = -\frac{GM_r}{r^2} \rho(1 - \alpha), \quad \alpha = \frac{2}{3} \left(\frac{\Omega^2 r^3}{GM_r} \right)$$

$$\frac{dM_r}{dr} = 4\pi r^2 \rho$$

where the symbols have their usual meaning.

The remaining stellar structure equations can be similarly averaged but are the same as the non-rotating equations to order α^2 . If α , the ratio of centrifugal force to gravity were constant throughout the star we could write $G^* = G(1 - \alpha)$ and the rotating structure equations are identical to the equations governing spherical star, in particular the relative variation of the physical variables is unchanged (that is T/T_c in terms of r/R for example), although their absolute value would be changed. Simple homology arguments then give

$$L \propto \frac{(\mu G)^8}{X^{1.2}}, \quad T_c \propto \frac{(\mu G)^2}{X^{0.4}}, \quad \mu = \frac{4}{(3 + 5X)}$$

where X is the fraction by mass of hydrogen; so that for $L = \text{constant} = L_\odot$, T_c changes negligibly and Σ_2 is only very slightly increased. On the other hand, if the angular velocity is constant α increases outwards and by scaling the models of Faulkner, Roxburgh and Strittmatter⁴ we see that for fixed L , T_c increases and Σ_2 increases more substantially.

These results, which are borne out by accurate calculations (to be published), suggest trying models where α decreases outwards; in such models the relative variation of the variables is changed—the temperature profile for example, is flattened, (Fig. 1). For such models we may expect a decrease in central temperature for a fixed luminosity and hence a decreased neutrino flux.

Fig. 1 The effect of non-uniform rotation on the temperature distribution inside stars. a , $\Omega^2 r^3/GM_r$ decreases outwards; b , $\Omega = 0$.

The Sun, of course, has evolved for some 4.7×10^9 yr and in inhomogeneous evolved models there are two factors lowering the neutrino flux compared with the standard models: first, the change in the temperature profile demonstrated previously; second, the increased homogeneity as compared to models with $\alpha = 0$ due to the increased region of nuclear burning caused by the changed temperature gradient. Detailed calculations show that these effects can reduce the

neutrino flux for the present Sun to less than 1 SNU (Table 1).

TABLE 1 Inhomogeneous solar model ($t = 4.7 \times 10^9$ yr; $L = L_Z/X = 0.019$)

	X_c	$\log T_c$	Σ_ϕ
$\alpha = 0$	0.35	7.17	6.5
$\alpha = \alpha^*$ (see Fig. 3)	0.50	7.11	0.93

In passing I note that it is no surprise that the calculation by Ulrich⁵ gave no substantial decrease in the neutrino flux. In his model Ω was constant and therefore α increased outwards in a core. It then dropped discontinuously to zero. We would not expect the right change in temperature profile from such a model.

The angular momentum per unit mass of interstellar gas clouds is so large that if a star forms it is highly probably that it will be rapidly rotating. Subsequent contraction exacerbates the problem; the central regions would spinup leading either to dynamic instabilities and possibly fission⁶

Fig. 2 Ratio of centrifugal force to gravity in a solar model before and after pre-main sequence contraction. *a*, End of contraction; *b*, Beginning of contraction.

or just a dynamically stable rapidly spinning core. Detailed calculations of contracting solar models including the effect of rotation have been made by Williams⁷ and in Fig. 2 I show the ratio of centrifugal force to gravity, α , after contraction. This angular velocity distribution is not stable to thermal perturbations, that is, those where radiative gains compensate for the stable stratification so that the fluid responds like an incompressible liquid^{8,9}. The instabilities on a scale l have growth rate given by

$$\tau = \tau_{th}(l/R)^2 1/\alpha, \quad \tau_{th} = 3GM^2/(4RL)$$

where τ_{th} is the thermal response time of the star $\sim 2 \times 10^7$ y. Since the Reynolds number is so large we must expect these instabilities to be turbulent and we can then estimate the mixing time by assuming a random walk process, requiring $(R/l)^2$ steps of length l . The mixing time is then the same for all models and is τ_{th}/α or about 10^8 yr.

During this time the chemical composition has changed due to the central burning of nuclear fuel, so there is now a chemical gradient which can stabilise an angular velocity gradient.

The angular velocity therefore adjusts initially to a marginally stable state in one or two mixing times and then continually readjusts as the Sun is slowed down by angular momentum loss in the solar wind. In the first stage there has to be substantial mass loss of about $0.3 M_\odot$. The results of detailed calculations are given in Fig. 3; the centre of the Sun is left spinning rapidly while the bulk is slowed down, α decreases outwards and this gives the low neutrino flux.

The external quadrupole moment has a value of about $J_2 = 6 \times 10^{-5}$, comparable with Dicke's measured value. The central region spins at a phenomenal rate with a period of about 50 min—it would be of considerable interest to look

Fig. 3 Angular velocity inside the Sun: *a*, after contraction; *b*, after re-adjustment; *c*, after solar wind braking. *c* is the distribution Ω^* used in the text.

for phenomena on the Sun with a period of 30 min to 1 h that might reflect this rapid motion; if it exists it might lend support to the "rapid core" explanation of the low neutrino flux.

Care should, however, be exercised before concluding that these models support the scalar tensor theories of gravity. In those theories the constant of gravity decreases in time which accelerates the nuclear burning and so increases the central temperature increasing the neutrino flux.

This work has been supported since April 1972 by the Science Research Council; a preliminary version was presented at the 1971 ESRO meeting in honour of H. Bondi.

Light curves of very faint meteors

THE variation of brightness as a function of height when a meteoroid burns up (ablates) in the Earth's atmosphere is governed by the physical properties of the meteoroid. The basic theory of the ablation of a solid meteoroid due to Öpik¹, and the theoretical light curves are in fairly good agreement with the observed light-curves of very bright meteors². In contrast to this the observations of Jacchia³ and Hawkins and Southworth⁴ of faint photographic meteors show that the train lengths of these meteors are much shorter than predicted by the classical theory, and it is principally due to evidence of this sort that the "dustball" theory of Whipple⁵ which supposes the original meteoroid to consist of an aggregate of many small solid particles, has become very popular. Nevertheless Jones and Kaiser⁶ found that by extending the classical ablation theory to include the effects of the meteoroid's thermal capacity, conduction and radiation they could explain many features of the experimental data in terms of compact meteoroids which fragment as a result of thermal shock. According to Jones and Kaiser⁶ it is possible to choose between the two theories on the basis of observations of very faint meteors (magnitude $M > +3$) since these meteoroids should not fragment due to thermal shock if they are compact; on the other hand if they are fragile conglomerates they will probably continue to show the effects of severe disintegration.

To this end we have developed an observing system⁷ using sensitive television equipment which has a limiting sensitivity of $+8.5$ mag for stars when operating with an $f/0.95$, 50 mm lens.

On the night of September 31/October 1, 1973 in London, Ontario, 179 meteors were observed with the system between 11 p.m. and 6 a.m. with the camera pointing north at an elevation of 50° .

Analysis of the video tapes enabled the train lengths perpendicular to the line of sight to be determined assuming the meteors to occur at an altitude of 95 km. The apparent train length l_a is related to the height interval between the starting and finishing height dh by the relation

$$dh = r l_a$$

where r is a random variable depending on the geometry of the camera and the meteor trains. Since at that time of year the activity of meteor showers is expected to be low, we tried two assumptions in order to estimate the mean value of r ; a random distribution of radiant and also a point radiant such that all the meteors were supposed to come from the apex of the Earth's way. Fortunately each of these assumptions yielded a mean value of r very close to unity.

Fig. 1. The difference dM between the magnitude of the meteors and the limiting magnitude of the observing system plotted against dh , the height interval between the starting and finishing height of the meteors.

In this way we obtained the results in Fig. 1 which shows dh as a function of dM , the difference between the magnitude of the meteor and the limiting magnitude of the system. For the sake of comparison we have also shown the theoretical predictions for the compact meteoroid model and the curve of dh against dM computed using the photographic data of Hawkins and Southworth.

It is clear that not only are the train lengths of the television meteors considerably shorter than predicted by the compact meteoroid model but they are also significantly shorter than those of the photographic meteors. We interpret this as indicating that fragmentation is even more severe for the very faint meteors than for the meteors of Hawkins and Southworth observed using Super-Schmidt cameras. On the basis of these results we conclude, albeit reluctantly, that the compact meteoroid model is no longer tenable.

Strong long-period tropospheric and stratospheric rhythm in the Southern Hemisphere

THE recent EOLE satellite-balloon atmospheric sensing experiment conducted in the Southern Hemisphere between August 1971 and July 1972, provided large quantities of upper tropospheric data in a hitherto near-dataless region. Besides measurements of ambient temperature and pressure reported directly from the balloon to the satellite, the experiment allowed the calculation of series of highly accurate Lagrangian velocities by the positioning of the balloon between successive satellite orbits. The experiment and data are described in detail by Morel and Bandede¹.

To obtain a Eulerian data set, the Lagrangian data required transformation. As no general analytical transformation exists², the Eulerian information was obtained by computing daily averages of all the measured Lagrangian quantities in each area of 10° latitude by 20° longitude. The resulting average was assumed to be the representative Eulerian daily average of that quantity. The rationale and justification of this method is given elsewhere (ref. 3 and P.J.W., D. G. Curtin and Y. Mintz, to be published).

Tropospheric rhythms: The many attempts to find a distinct atmospheric periodicity on a global or hemispheric scale have met with little success. Most notable are the efforts of Willett⁴ and Namias⁵ in the Northern Hemisphere and recently by Taljaard⁶ in the Southern Hemisphere. All studies defined some index which was more or less sensitive to the change of state of the atmosphere. Although large variations in the various indices did occur, no dominant rhythm was identified⁶.

Another common feature of these studies was the use of land based Eulerian sensors which, on account of their geographical grouping, may not have been suitable for the calculation of a representative hemispheric index. To overcome this problem, the Eulerian data inferred from the dense EOLE data set was used to define a zonal index sensitive to the transition of the atmosphere from perturbed to a zonal state. Such an index (R) is defined as the ratio of the kinetic energy of the mean flow (K_z) and the zonal average of the perturbation or eddy kinetic energy (K_E), that is,

$$R = K_z / K_E = \frac{1}{2 \cos \phi} \int_0^{2\pi} (\bar{V} - [\bar{V}])^2 d\lambda / ([\bar{V}]^2 / 2)$$

where

$$[\bar{V}] = \frac{1}{\cos \phi} \int_0^{2\pi} \bar{V} d\lambda.$$

Here λ represents longitude, ϕ latitude and \bar{V} the distribution of the daily mean Eulerian velocity inferred from the EOLE data.

Time sections of R are shown in Fig. 1 for three 10° latitude bands between 30° and 60°S. Large amplitude variations may be seen with an apparent period of some 20 d, especially in the higher latitudes. These represent regular changes from highly perturbed states (large R) to highly zonal states (small R). Superimposed upon this trend are variations of higher frequency and smaller amplitude indicating similar but short lived variations.

The times series spectral analyses of $R(t)$, shown in Fig. 2, tend to support these observations. In the 50°–60°S latitude spectra for R , a strong isolated peak suggests a strong rhythm centered near 20 d in the high latitudes, a feature which is also reflected in the K_E spectra. As illustrated by the 40°–50° spectra of R , the peak is somewhat weaker and further diminishes into the subtropics. Spectra of the zonally averaged pressure (lower diagram) indicates a weaker periodicity near 20 d, whereas the zonally aver-

Fig. 1 Variation with time of the index R over the EOLE period for the three latitude bands indicated.

aged temperature field does not exhibit relatively as large a variation. This is common to the temperature field at all latitudes.

The cross spectra between the two component energies of $R(t)$ indicate an extreme peak near 20 d. An important feature is that, in the 50° to 60° band, K_E and K_z are almost exactly out of phase (-176°) and have a coherence of 0.825 in the 18 to 23 d band, surpassing the 99.9% confidence limit at this spectral band width. (Coherence between the various values of R for the different latitudes each

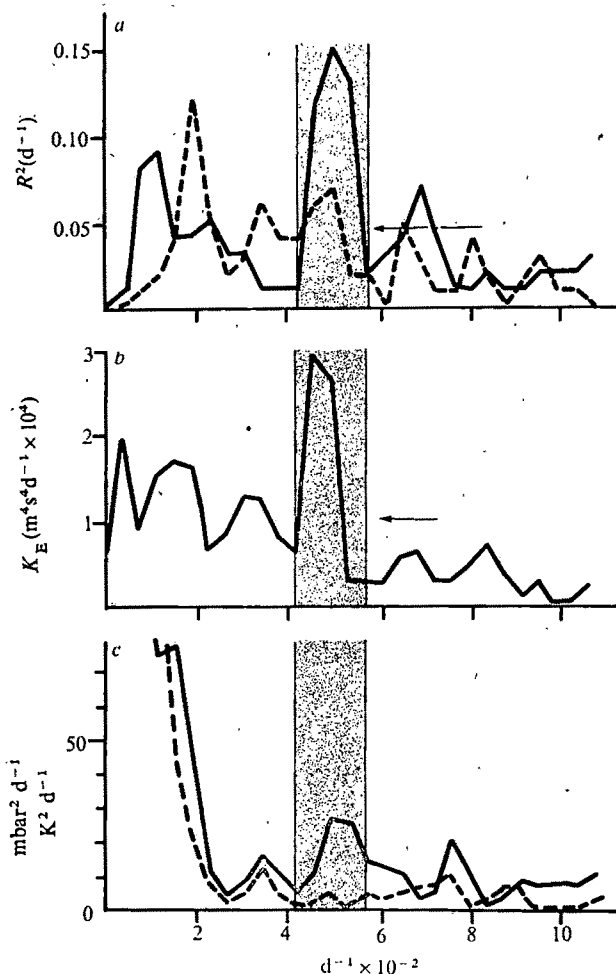

Fig. 2 Variance spectra. *a*: —, R for 50° to 60°S; ---, R for 40° to 50°S. *b*: K_E for 50° to 60°S. *c*: —, P ; ---, T . Both for 50° to 60°S. Arrows denote 90% confidence level, shaded region the 18 to 23 d band.

surpasses the 99% level in this frequency band.) Such phase and coherence strongly suggests that the quasi-20-d rhythm in R may be accounted for by the conversion of kinetic energy between that of the eddies and that of the mean flow, such that the cycle consists of waves growing at the expense of the mean flow and then the reverse conversion.

Spectral analysis in space and time indicates that much of the power of the 20-d rhythm is in the ultra-large scale waves. For example, in the 50° to 60° band, the kinetic energy in longitudinal wave numbers 1 and 2 is an order of magnitude greater in the 18 to 23 d period interval than for any other wavenumber. The momentum flux also shows a 20-d rhythm, which, together with the above, suggests that this variability in R is a manifestation of a slow period and very large scale barotropic energy conversion between K_n and K_z which is similar in character to the barotropic energy conversion described by Lorenz⁷. But this process is generally thought to be restricted to a much smaller scale ($\sim 1,000$ km) and higher frequency motions (~ 4 to 5 d) and is considered to be of secondary importance in the energetics of the general circulation.

In contrast, we suggest that the precominant process in upper-troposphere of high latitudes over the time scale of weeks is the barotropic exchange of energy between the ultra-long waves and the zonal flow.

(ii) Stratospheric rhythms: Initial attempts have been made to determine to what extent the stratosphere is effected

by the large scale, long period tropospheric oscillations suggested above. Due to the scarcity of conventional data and the consequent inability to construct a zonal index for the stratosphere, total ozone data from the few scattered Southern Hemisphere stations were analysed.

Figure 3 shows the time series spectral analyses of the total ozone for the three stations, Argentine Island (65°S), MacQuarie Island (55°S) and Brisbane (28°S) chosen for the initial study on the basis of data availability and latitudinal spread. The only data modification was the removal of the dominating annual trend before the spectral analysis.

The common feature of all three spectra is the existence of power, to varying degrees, in the 18 to 23 d period band. This is especially evident at Argentine Island and MacQuarie Island, and surprisingly for a station so far equatorward, at Brisbane. Cross spectra between these ozone stations show strong coherence during the EOLE period in the 18 to 23 d band. The coherence between R and the stratospheric ozone is slightly weaker but this may be because we are seeking cross-spectra between point observations (the ozone) and hemispheric quantities (R).

The results presented here are not conclusive, but there seems to be a strong suggestion of a preferred and dominating physical mechanism existing over the period of weeks in the high latitudes of the upper troposphere of the Southern Hemisphere. This large scale and long period oscillation seems to be tied to the barotropic interchange of energy between the perturbations and the mean flow and possesses vertical propagation properties such that it may provide an important energy source for the stratosphere over this time scale.

Dispersion of ionospheric waves

THE phase speed dispersion of travelling ionospheric disturbances (TIDs) has been measured using data from a three-dimensional array of c.w. Doppler sounders¹. Horizontal and vertical trace speeds of phase surfaces were measured as a function of wave period by performing cross-spectral analysis of the array signals. Although the measured dispersion varied considerably depending on the coherence of the wave activity across the array, the average horizontal trace speed was approximately proportional to $T^{-1/2}$, where T is the period. From a very limited set of measurements, vertical trace speed was tentatively determined as proportional to T^{-1} . Additional measurements of highly coherent waves now indicate that the vertical dispersion is even stronger than T^{-1} at the short periods (12-25 min.).

Based on the reliably determined horizontal dispersion and a large diurnal variation of speed, I suggested¹ an

explanation of the observations in terms of hydromagnetic waves. This explanation did not account for the magnitude of the observed speeds but explained the horizontal dispersion and large diurnal variation of speed. Because of the difficulty of developing a satisfactory hydromagnetic wave explanation, I attempt here to show how the dispersion could be accounted for in terms of the widely accepted internal gravity wave explanation of TIDs (ref. 2).

The horizontal of phase speed gravity waves is a function not only of period but also of the tilt of the phase surfaces away from the vertical:

$$V_x = \frac{c}{\omega_0} [N^2 - \omega^2(1 + \tan^2 \phi(\omega))]^{1/2}$$

where N , ω_0 and ω are the Brunt, acoustic cutoff and wave frequencies, c is the speed of sound, and $\phi(\omega)$ is the tilt of the phase surfaces away from the vertical¹. As the phase surfaces tilt over towards the theoretical limiting angles of wavefront tilt, given by

$$\phi_L = \tan^{-1} \left[\frac{N^2}{\omega^2} - 1 \right]^{1/2}$$

the horizontal speed, V_x , approaches zero. When ϕ is zero (no tilt), or when ϕ is a fixed percentage of the limiting angle, V_x increases toward long periods. If, however, a wavefront tilt function, $\phi(\omega)$, is chosen in which phase surfaces tilt over closer to the limiting angles at long periods than at short periods, V_x can be made to decrease towards long periods. That is, the first equation above can be solved for $\phi(\omega)$ giving:

$$\phi(\omega) = \tan^{-1} \left[\frac{N^2}{\omega^2} - 1 - \frac{\omega_0^2 V_x^2}{c^2 \omega^2} \right]$$

For any specified horizontal phase speed dispersion, $\phi(\omega)$ will be less than ϕ_L and both will increase toward long periods with $\phi(\omega)$ approaching ϕ_L if V_x decreases toward long periods.

Figure 1 shows new observations of the mean horizontal and vertical phase speeds of ionospheric waves recorded between 1700 and 2200 LT on four successive days (November 22-25, 1972) in the New York City area. The horizontal speeds were determined from an array of four Doppler sounders operating at 4.5 MHz. The vertical speeds were determined from the phase lags of the downward-moving wavefronts between the reflection levels of 4.5 MHz and 2.5 MHz Doppler sounders. The absolute values of the vertical speeds are difficult to measure accurately because the difference in the reflection level of the two radio frequencies varies over the recording interval of 5 h. An average vertical separation of 20 km was however estimated using mean monthly electron density profiles for November 1972, at Wallops Island, Virginia, which is several hundred kilometers south of the array.

Both horizontal and vertical speeds decrease toward long periods. The observed phase speed dispersion can be best approximated by gravity wave theory if it is assumed that the waves propagate with the wavefront tilt given by the dotted line at the bottom of fig. 1. A Brunt period of 8 min was assumed which gives the limiting angle of tilt, ϕ_L , in fig. 1. The theoretical V_x and ϕ determine the theoretical V_z since $V_z = V_x / \tan \phi$. The theoretical speed decreases towards long periods because the theoretical value of ϕ approaches ϕ_L at long periods. The observed wavefront tilt is also shown. It does not entirely match the theoretical tilt function, but as required, is closer to the limiting angle at long periods. Either the observed V_x or V_z could be approximated more closely by a different theoretical tilt function but the best approximation to both is shown.

For the time of day of the observations, the radio signals from the Doppler sounders should have reflected near 200 km height, where the Brunt period is about 14 min for a

Fig. 1 Mean horizontal and vertical phase speeds and tilt angles of ionospheric waves recorded between 1700 and 2200 h LT on four successive days (November 22-25, 1972). Standard deviation bars are shown. Theoretical speeds and tilt function, consistent with gravity wave theory when the limiting tilt angle ϕ_L is assumed, are also shown. a, V_x theoretical; b, V_x observed; c, V_z theoretical; d, V_z observed; e, ϕ , theoretical; f, ϕ observed; g, limiting tilt angle.

1962 US Standard Atmosphere. The best fit of theoretical and observed curves was however, found using atmospheric parameters (N , ω_0 , c) that apply to about 125 km.

Theoretically, free interval gravity waves tend to propagate energy at increasing angles ($90^\circ - \phi_L$) about the horizontal, as period decreases³. If however, a broad spectrum of waves from a single source were observed at a receiving point, then the short period waves would necessarily have travelled at lower percentages of their limiting angles than did the long period waves, thus producing the apparent inverse dispersion. Figure 1 indicates that over a wide range of periods, the wavefront tilts need be only a few degrees less than the limiting angles to produce the observed dispersion.

A large diurnal variation of the phase speed of the F-region waves has been reported⁴. The speeds increase hundreds of per cent from day to night, maintaining the apparent inverse dispersion. Although it is difficult to explain why, I suggest that for some reason the waves simply propagate at angles further from the limiting angles at night, causing larger phase speeds at all periods.

It would be useful to use a very widely spaced array and attempt to measure group speeds of a sufficient number of waves to detect group speed dispersion and any diurnal variation of group speed. Such measurements are, however, probably much more difficult than accurate phase speed measurements. According to gravity wave theory, horizontal group speeds must be less than phase speeds. My suggestion¹ that the observed horizontal dispersion implies a group speed greater than the phase speed¹, would be invalid for the strongly anisotropic behaviour of gravity waves. As indicated here, the apparent inverse phase-speed dispersion could result

solely from the behaviour of the wavefront tilt and thus the slope of the phase-speed dispersion curve would give no information about group speeds.

Brownlie *et al.*⁵ have reported ionospheric wave measurements which suggest higher phase speeds at the longer periods, and they noted the discrepancy with the observations of Herron¹, such as shown in fig. 1. The speeds, however, vary considerably with time of day⁴, and if care is not taken to eliminate this effect, it could distort the dependence on period.

Will another damaging earthquake occur in Koyna?

AN earthquake of magnitude 5.1 (Richter scale) occurred on October 17, 1973, near the Koyna Dam (17°23'N, 73°45'E) which experienced a damaging earthquake¹ on December 10, 1967. The former earthquake was preceded and followed by several foreshocks and aftershocks. Two of the foreshocks on the same day had magnitudes of the order of 4.0 and there was another significant earthquake of magnitude 4.6 in the same region on October 24.

It is now well known that filling of large artificial lakes behind high dams can trigger earthquakes²⁻⁴. The examples of Kariba, Kremasta and Koyna are particularly significant since damaging earthquakes of magnitude exceeding 6 have occurred in these regions.

Before the construction of the Koyna Dam in the western part of the Peninsular Shield of India no significant tremor had been recorded. Soon after the impounding of the Koyna reservoir in 1962, reports of earth tremors near the dam site began to accumulate. Thereafter thousands of tremors were located within 25 km of the dam by a network of four closely spaced seismological observatories⁵. Up to June 1969, 450 of these shocks had magnitude ≥ 3 . The earthquake of September 13, 1967 (magnitude 5.5) was the

first significant event and caused mild damage in Koyna Township. The earthquake of December 10, 1967 had a magnitude of 6.0, claimed about 200 lives and caused widespread damage. The earthquake of October 17, 1973 (magnitude >5) occurred in the Koyna region after a lapse of 5 yr, the last one having occurred on October 29, 1968. An analysis of the records of the Hyderabad seismograph station, situated about 490 km east of the Koyna Dam, shows that the frequency of earthquakes of magnitude ≥ 4.0 has decreased during the past few years following that of December 10, 1967. Table 1 shows that nine such earthquakes occurred in 1969, seven in 1970, four in 1971 and three in 1972. Between January and September 1973 only one earthquake of magnitude 4.1 occurred (on April 19). During October 1973 three earthquakes of magnitude >4 occurred in addition to the one of magnitude 5.1. The present activity does not fit the trend of gradually decaying seismicity in the Koyna region during the past few years.

From studies of reservoir levels and earthquake frequency at several places⁴ it has been inferred that, in addition to the tectonic setting and geological conditions, the factors affecting the tremor frequency near the reservoirs include (1) the rate of increase of water level; (2) the duration of loading; (3) the maximum level reached; and (4) the period for which high levels are retained. These observations are supported by a statistical analysis of the water level and earthquake frequency for the Lake Mead⁶, Koyna,

FIG. 1 Three-monthly average of water levels and total numbers of earthquakes for the same months at Koyna (a), Kariba (b) and Kremasta (c) for which the correlation coefficients are +0.93, +0.74 and +0.69, respectively. The periods include 1964 to 1968 for Koyna, 1959 to 1968 for Kariba and July 1965 to June 1966 for Kremasta. 1. Water level; 2, frequency.

Kariba and Kremasta reservoirs. In Fig. 1, for the latter three cases, water levels are given as averages over 3 months and the earthquake frequency as the total number of earthquakes registered in the same months for the whole of the period considered. The correlation between water level and frequency is readily apparent. Using other averages and monthly combinations, however, the correlation is less apparent and the high activity before and after the main shock greatly affects the frequency curve. Among the many examples of reservoirs with associated seismicity Koyna is the most outstanding; earthquakes occur whenever high levels are reached following rapid filling and are retained for long times. The highest water levels were maintained for longest⁷ during August to December 1967, corresponding well with the maximum seismic activity and the earthquake of magnitude 6.0 on December 10, 1967. The second highest level was reached during August to October 1965, which corresponds well with the second most conspicuous period of activity (during November 1965).

Reservoir levels in the Koyna Lake have been kept relatively much lower since December 10, 1967. No major earthquakes have occurred since October 1968 and this year water has again been allowed to accumulate in the reservoir, which was filled completely for the first time on August 15, 1973. The consequent high seismic activity included an earthquake of magnitude >5 and very strongly supports the idea of a persistent relationship between water level and earthquake activity.

The earthquake of October 17 is similar to that of September 13, 1967. The two earthquakes had comparable magnitudes, originated at the same place, had a similar foreshock-aftershock pattern and occurred after rapid filling of the reservoir to peak levels. Although it cannot be said with certainty that the present seismic activity heralds a strong earthquake in the Koyna region, there is a definite enhancement in the seismic activity which correlates with the increased reservoir levels.

Gradient of caesium in the ocean

THE major alkaline metals are extremely uniformly distributed in oceanic water relative to other solutes. Caesium occurs in the ocean in such small traces, however, that precise analysis has in the past been difficult and its distribution in the sea has remained in doubt. Samples collected at seven depths in the North Pacific in 1970 were measured using a differential flame photometer, which indicated, that caesium concentrations in the open North Pacific vary by no more than about 2% between depths of 0 and 4,000 m (ref. 1). Unfortunately, this earlier analytical procedure, and others in use, are incapable of demonstrating the still smaller anom-

alies and concentration gradients that must exist in an ocean that continues to transport caesium from its terrestrial rocky sources to the seafloor.

Less is known about the long term steady state of progress of the natural non-radioactive nuclide ¹³³Cs through the ocean, than is known about the progress of the radioactive nuclides of caesium that have entered as nuclear fallout during the last decade. It would be reassuring to understand, for instance, how fast the surface layers of the ocean might dissipate the relatively larger amounts of ¹³⁷Cs that may enter as a consequence of the use of fissionable fuels.

Recently, analytical equipment specialized for traces of natural caesium was completed at the Scripps Institution² and tested with carefully collected North Pacific water samples. These measurements seem to demonstrate for the first time a significant difference between the caesium concentrations at the sea surface and in the deeper water. They also emphasise the uniformity of caesium concentrations in deep Pacific water masses, and the extreme similarity of caesium concentrations, normalised against salinity, at Pacific surface stations thousands of miles apart.

In essence, the new procedure is a computerised version of emission flame spectrometry, used after relatively large (2 l) samples have been concentrated by multiple extractions using the methods of Feldman and Rains³. Standard amounts (spikes) of caesium are added to alternate halves of each unknown and each reference sample, which are extracted in special gang tumblers⁴. A new form of sample changer which uses an automated distributing valve² burns the unknown spiked and unspiked concentrates, as well as the spiked and unspiked concentrates of 'reference standard seawater samples' in uniform succession. Burning of each of the four concentrates is done on six portions alternatively, and is programmed by a digital system tied into a desktop computer (Wang 600).

This allows standardising assays (on 10 ml organic concentrates containing 0.3 µg caesium) to be replicated with standard deviations < 0.3%. At present, the standard error of replicating the complete comparison between two seawater samples is somewhat more, about 0.5%. Two to eight replications are, however, made.

Figure 1 summarises concentrations and positions at six North Pacific stations. Caesium determinations are normalised to a salinity of 35.00 parts per thousand and the bars give the standard deviation of the mean of assays for each sample. In August 1973 at stations 1 and 2 small (4 l) samples were collected at depths of 0, 1,000, 2,000, and 4,000 m. At station 1, a large (50 l) poly carboy of surface water was collected for tentative reference. Large samples were also collected at stations C and D, about 2,000 miles apart. The normalised means of caesium concentration for these three large recent samples differed little, 0.0005 (0.2%), from a mean value of 0.2990 µg kg⁻¹.

The (large) 3-year-old samples, A and B, had concentrations departing from this mean less than might be expected from (wall) losses, and the two smaller surface samples, 1 and 2, differed only as predicted statistically.

Figure 1 indicates a downward decrease of natural concentrations of caesium in the open North Pacific Ocean. It is too early to discuss the differences apparent between 1,000 m and 4,000 m, but the mean of all (12) subsurface analyses of the six samples collected at 1,000 m or below is 0.295 µg kg⁻¹ and the difference between this and the surface mean is 0.004 µg kg⁻¹ (1.4%). This seems to be a significant measurement, of interest to oceanographers.

Caesium, of all the alkali metals, has the shortest mean residence in the ocean, about 0.9 m.y. (ref. 5). Concentrations in typical deep sea sediments, 0.9 p.p.m., (ref. 5), imply steady transport rates that are quite consistent with mid-water concentration gradients implied by the data summarised in Fig. 1. For example, if simple constant-coefficient diffusion

FIG. 1 Variations in natural caesium (^{137}Cs) concentrations in the North Pacific (normalised to salinity 35.00‰). The map shows positions of the stations sampled: A and B in 1970; C, D, 1, and 2 in summer 1973. Precision for caesium measurements had to be greatly advanced to make these comparisons. Tentatively a mean value of $0.299 \mu\text{g kg}^{-1}$ of Cs for North Pacific surface water was concluded. Deep water seems to have 1.4% less caesium. a, Temperature; b, salinity; open and hatched circles, deep station 1; +X, deep station 2.

through an ocean 'cap' 1,000 m thick is tentatively considered, a mean coefficient of 0.2 is required. Thinner 'caps' require correspondingly smaller diffusivities which range within values suggested by several other midwater studies⁶⁻⁷. Further assurances come from finding that the changing vertical concentration profiles⁸⁻⁹ of fallout radiocaesium, ^{137}Cs , are consistent with mixing rates approximately expressible by coefficient of these magnitudes, as are the changing concentrations of radioactive caesium observed in tissues of oceanic fish during the past decade¹⁰.

The mean surface value of $0.299 \mu\text{g kg}^{-1}$ seems free from absolute bias to well within 1%. Studies of chemical blanks and the linearity of signals with concentrations are, however, being further investigated to refine this absolute measurement. It is now evident, from comparisons of 1970 samples A and B with recent samples C, D and 1, that the large storage losses previously feared may be overcome, although to what extent is still uncertain. It is, nevertheless, evident that investigations of oceanic caesium should be referred to large contemporary samples of seawater of well established salinities, preferably deep water samples.

Change in the current regime in the Suez Canal after construction of Aswan High Dam

Morcos and Messieh¹ attempt to confirm conclusions by Morcos², exemplified by the statement "Comparison with older data from the Canal in September 1924, September 1933, September 1954 and September 1964 showed that a complete reversal of the current regime at that time [September 1966] had taken place."

In their recent letter¹ other observations of 1966 were presented which, they claimed, 'confirm that the southward current which has hitherto occurred in the Canal every summer, did not occur in the summer of 1966 and that the current remained northward during the whole year.'

It is difficult to see how such a statement could be maintained in face of El Sabh's^{3,4} observations of September 1966. In Morcos and Messieh's words describing El Sabh's observations "The northern part of this section, unlike Morcos's section, shows that the northern part of the canal was filled with Mediterranean water." Noting that this northern part is more than 70 km long, Morcos and Messieh's self-contradiction becomes apparent, as the Mediterranean water could not conceivably penetrate that far south, with a northgoing current prevailing all year round.

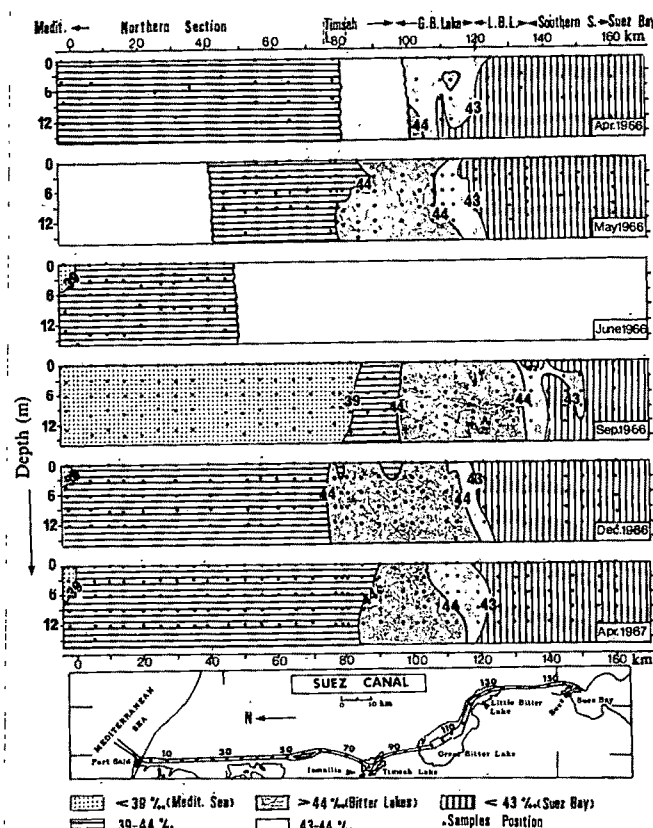

FIG. 1 Salinity with depth section of the Suez Canal in 1966, showing positions of stations and depths at which samples were taken.

The explanation is that Morcos's observations on September 29–30, 1966 were made after the normal September situation has ceased and the northgoing current resumed flowing.

As to their assertion that the net current in the southern part of the Canal was also northgoing, based on observations that the Great Bitter Lake (GBL) water did not reach the Suez Bay, this is also a conclusion not warranted by the evidence advanced.

For the GBL water to reach the Suez Bay, it has first to fill the Little Bitter Lake, then fill the southern Canal and only then can it be detected in the Suez Bay. But it can move southwards to the Little Bitter Lake, the southern part of the Canal and even into the Suez Bay. The southern limit of GBL water will depend upon the net speed and duration of the motion. Comparing the September 1966 observations with those in May and December 1966 (Fig. 1) the GBL water has moved south to fill Little Bitter Lakes in September. Because the cross-sectional area of the Little Bitter Lake is five times the mean cross section of the Canal proper, the filling of this lake (~15 km long) is equivalent to filling about 75 km of the Canal proper. It is admitted that the southern motion was not as strong in 1966 as previously observed, but it would be a mistake to insist that it did not occur.

Our conclusion is that the usual reversal of the Suez Canal regime occurred during 1966, as it did in previous years. The magnitude of the reversal in that year was not as great as previously observed, and further observations are necessary to establish the magnitude of the influence of the cessation of the Nile flood on that reversal, but certainly it did not stop it.

DR MORCOS replies: Hassan and El Sabh compare one season with another by using their five sections of 1966. My approach is to study the seasonal cycle of 1966 in the light of the seasonal observations made during the preceding years, with a view to detecting any change that could have taken place after the construction of the Aswan High Dam.

Between 1933 and 1937, the scientists of the Suez Canal Company conducted an extensive 'quantitative' study of the water regime of the canal by registering the mean water level and currents using five tide gauges and two continuous recording current meters north and south of the Great Bitter Lake. Baussan¹ concluded that between the northward current in winter and the southward current in late summer, there is a transitional period during which the current is only reversed in the northern canal. Thus

water flows from the Mediterranean to the Bitter Lakes while the current in the southern canal continues to flow northward from the Red Sea to the Bitter Lakes. Examples given by Baussan were July–August 1935, June, July, August 1936, and June 1937. In these months the water flowed from both ends of the canal towards the Bitter Lakes. This is the most likely regime since, according to Miller and Munns², compensation must be made for the high evaporation from the Bitter Lakes during this season. Thus, Hassan and El Sabh's observation that Mediterranean waters penetrated 70 km into the northern canal does not necessarily imply that the current throughout the canal (the net out-flow) was southwards.

My studies³ of current measurements in the promontory of Kabret, between the two basins of the Bitter Lakes, indicate that the resultant currents are much weaker and less variable in magnitude and direction, and may even show a sign opposite to that of the stronger currents in the southern canal. The water mass of the Great Bitter Lake (GBL) increases in volume and salinity in summer because of high evaporation and slow currents over the salt bed^{4,5}. This is most easily observed in transitional periods when water flows from both ends towards the Bitter Lakes as a result of the long residence time over the salt bed. The Little Bitter Lake (LBL) is an integral part of the Bitter Lakes Basin and in the absence of a strong northward current is filled by the water mass of the GBL as a result of the expansion of this water mass in volume and its increase in salinity. This is enhanced by diffusion and turbulence processes and should not be taken as evidence of a southward current in the canal, as suggested by Hassan and El Sabh. A similar distribution, showing that the LBL filled with GBL water mass, was observed in August and November 1931, July, August, October and November 1933, June and July 1935 and June 1955. These are months with transitional characteristics or even a weak northward current.

In the various parts of the Suez Canal, currents change direction over periods of hours and days as a result of tidal and non-tidal factors. The main seasonal criterion, however, is the net outflow from the canal, which quantitatively defines the current regime. This is probably an appropriate expression of the final resultant of the complex system of currents in the canal.

Continuous recording of currents at two points in the southern and northern canals has quantitatively demonstrated a net outflow into the Mediterranean Sea during most of the year and a net outflow into the Red Sea during late summer. For example, in 1935 there was a net outflow of $5,250 \times 10^6 \text{ m}^3$ into the Mediterranean during the first period, and of $150 \times 10^6 \text{ m}^3$ into the Red Sea during the second period⁶. Passing through the Great Bitter Lake, this latter outflow greatly increases the salinity in the Suez Bay during August and September every year. It has been demonstrated that such an increase in salinity did not take place at all during 1966⁷ and it can be safely stated that the net outflow from the canal into the Red Sea previously observed every late summer, did not occur in the summer of 1966.

Finally, Hassan and El Sabh admit that an unusual phenomenon occurred in the current regime in the Suez Canal during 1966 and that "further observations are necessary to establish the magnitude of the influence of the cessation of the Nile flood on the reversal of the current". In their view, this unusual phenomenon is only a change in the magnitude of the reversal, whereas it is, according to the evidence present here, a fundamental change in the seasonal pattern of the current regime. My conclusion is that the northward current regime in 1966 was followed by a transitional period with water flowing from both ends to the Bitter Lakes. By mid September the current had

regained its northward direction without being reversed to the south.

Time-dependent viscosity effects measured on an impact microviscometer

THE viscosity of a fluid has been shown by conventional viscometers to rise approximately exponentially with pressure. Such viscometers always require a long period of time to build up the pressure on the fluid, typically an hour or more to reach pressures common in elastohydrodynamic contacts. Since a typical residence time for a fluid in a contact would be less than 0.01 s, Fein has suggested that fluids might not reach equilibrium viscosities instantaneously¹. Until now there has been no direct experimental evidence to support this suggestion.

We have already published some viscosity-pressure data measured on an impact microviscometer², and Hutton and Phillips have found the viscosity-pressure characteristics of one of the fluids using a Couette viscometer³. A large discrepancy is seen when the two sets of results are compared, except at the very low pressure end. Above 60 MN m⁻² the discrepancy increases steadily until, at the highest pressure reached, there is a difference of almost four decades in viscosity. We suggest here a reason for this enormous discrepancy.

The technique used to determine viscosity has been described². In brief, the elastohydrodynamic film of liquid trapped between a flat surface and a loaded ball is measured using a new interferometric technique. From the variation of film thickness with position and time the viscosity can be calculated using Reynolds equation in polar co-ordinates.

The pressure field is found from the elastic deformation of the surfaces. The shear stress τ , given by $\tau = (1/2)h\delta p/\delta r$, is quite large, reaching 50 MN m⁻². These stresses might cause the fluid to be non-Newtonian (K. L. Johnson, personal communication) thus explaining the difference between our results and those of ref. 3. In the dimple the shear stresses rose to a maximum at about $r = 0.3R$ (where R is the radius of the entrainment measured from the centre), and fell to zero at the centre where $\delta p/\delta r = 0$ and at the edge where h is small.

If the critical shear stress, above which the liquid is non-Newtonian is less than the maximum shear stress, the viscosity measurements would only be correct near the centre and edge of the entrainment, but would be too low in the intermediate position. Typical viscosity measurements with the impact microviscometer show very little increase of viscosity with pressure in the high pressure regions, the viscosity measured at $0.3R$ is very much the same as the viscosity near the centre. Taking into account a shear stress

effect lowering the effective viscosity would mean that the 'true' viscosity is considerably larger than the observed values in the intermediate region. This implies that 'true' viscosity reaches a peak as the pressure is increased and then falls at the extreme high pressures, which is most unlikely. Thus it is reasonable to conclude that the shear stresses here are not high enough to cause non-Newtonian behaviour in the fluid.

The next factor to be considered was whether there could be any time dependence of the viscosity on the pressure step imposed by the ball. In previous measurements there appeared to be no systematic variation of results taken at successive intervals of time as the fluid leaked out of the entrainment. It was realised however, that compared with the time intervals of the measurements these results were taken a long time after the pressure step was applied.

The viscosity of one fluid was therefore measured using a ciné-camera at 400 frames s⁻¹ to obtain viscosity measurements at times from 0.01 to 5 s after the imposed pressure step. Some results were also taken on a new apparatus which, by using a plate made of sapphire instead of glass, tolerates much higher pressures. Because of the higher pressure, the fluid took much longer to flow and results could be obtained at times of up to 200 s after the pressure step. The results for the chosen fluid, a paraffinic cylinder stock B P 10.65, are shown in Fig. 1. There is a definite time delay of the viscosity rise after a pressure step. At 800 MN m⁻² the viscosity varies from 3×10^4 N s m⁻² after 0.015 s, to 3×10^8 N s m⁻² after 105 s.

The polyphenyl ether tested in the earlier experiments^{2,3} was then measured at the longest possible time after the pressure step to see if there would then be a better correlation with the results of Hutton and Phillips. The new results, together with the earlier ones^{2,3} are shown in Fig. 2. The new results show a better correlation although the curves still diverge at a pressure of 150 MN m⁻². This is to be expected since the technique of Hutton and Phillips² requires a considerably longer time to reach this pressure than the 130 s in our experiments, so the discrepancy in the results can probably be attributed to time-dependence effects. Also included in Fig. 2 for comparison is a viscosity-pressure characteristic obtained for polyphenyl ether 5P4E⁴. This was derived from traction data on the fluid as it passed through a rolling/sliding elastohydrodynamic contact at 99° C and therefore refers to time scales of much less than

Fig. 1 Variation of viscosity with pressure of fluid BP 10.65 paraffinic cylinder stock, showing time delay of viscosity increase after a pressure step. The figures following each curve indicate the amount of time which has elapsed (s) since the first photograph (see text). a, Viscosity measured on a conventional viscometer.

Fig. 2 A comparison between the new results and results obtained in earlier experiments. *a*, Fluid 5P4E at 23° C after 130 s; *b*, fluid 5P4E at 23° C after 5 s; *c*, fluid 5P4E at 99° C, derived from traction data⁴; *d*, fluid 5P4E measured on a Couette viscometer³.

our results in Fig. 2. No direct comparison can, therefore, be made but it is interesting to note that the same general behaviour is found.

In conclusion, it seems that time-dependent variation of viscosity following a pressure step, first proposed by Fein¹, has been experimentally established. This will have a profound effect on estimates of viscosity inside elastohydrodynamic contacts. We are now investigating the time dependence for other fluids.

This work has been supported by the Science Research Council and the Office of Naval Research. British Petroleum provided the conventional viscosity measurements.

Surface structures of gibbsite goethite and phosphated goethite

INFRARED studies of surface hydroxyls on solids of high area have been limited to almost anhydrous materials prepared at elevated temperatures. These studies have made an important contribution to the understanding of surface catalysis, but have little relevance to adsorption processes that occur on moist surfaces at ambient temperatures. Such processes contribute to a wide range of everyday phenomena, including the retention of fertilisers and pesticides in soils.

Here we establish that the surfaces of the crystalline hydroxides gibbsite (γ -Al(OH)₃) and goethite (α -FeOOH), both common soil components, are accessible to infrared study, and that their surface structures are well defined and closely related to their bulk structures. The observation of

Fig. 1 Infrared absorption of surface Al-OD groups on the (001) face of gibbsite in the form of a polycrystalline film (6.2 mg cm⁻²). Weak bands at 2,762 and 2,750 cm⁻¹ may arise from Si-OD of adsorbed silicic acid; the band at 2,610 cm⁻¹ is due to bulk OD.

these surface hydroxyls opens the way to the study of their involvement in surface reactions.

Electron microscope analysis shows the synthetic gibbsite¹ was in the form of thin hexagonal plates of diameter about 250 nm and thickness 9 nm. Their surface consisted principally of (001) faces with a calculated area of 96 m² g⁻¹, whereas edge faces represented only 8 m² g⁻¹. On evaporation from suspension, this material formed excellent self-supporting films with the crystal plates parallel to the film plane.

The infrared spectrum of this gibbsite is dominated in the 3,000 to 4,000 cm⁻¹ region by absorption due to the stretching vibrations of bulk hydroxyl groups, which give bands at 3,622 cm⁻¹ and 3,529 cm⁻¹ polarised in the (001) plane, and a third at 3,460 cm⁻¹ polarised perpendicularly to that plane. Gibbsite consists of infinite planes of close-packed hydroxyl groups parallel to (001), the planes being bound together in pairs by aluminium ions to form a layer structure. Thus the perpendicular 3,460 cm⁻¹ band can be correlated with hydrogen bonds between layers (2.82 to 2.87 Å long²) and the 3,622 cm⁻¹ and 3,529 cm⁻¹ bands correspond to longer hydrogen bonds between hydroxyls within the same plane (3.29 Å and 3.13 Å long according to ref. 2; a longer in-plane OH-OH separation of about 3.38 Å probably involves no interaction).

Absorption by these bulk hydroxyls largely obscures the absorption bands of surface Al-OH groups, but a brief (10 s) treatment of a gibbsite film with D₂O followed by evacuation revealed surface Al-OD groups absorbing at 2,726 cm⁻¹, 2,682 cm⁻¹ and 2,655 cm⁻¹ (Fig. 1), which were lost again immediately on exposing the films to water vapour. The corresponding frequencies of surface Al-OH groups would be 3,690 cm⁻¹, 3,629 cm⁻¹ and 3,588 cm⁻¹ but only the first can be seen in evacuated films because of the strong absorption by bulk hydroxyl groups. All three surface absorption bands are polarized in the plane of the layers, so the OH groups that were involved in interlayer bonding within the crystal (absorbing at 3,460 cm⁻¹) must link OH groups within the surface plane, and probably absorb at 3,690 cm⁻¹. This weak interaction leads to a lengthening of other in-plane OH-OH separations, so that hydroxyls that absorb at 3,529 cm⁻¹ and 3,622 cm⁻¹ within the crystal absorb at 3,588 cm⁻¹ and 3,629 cm⁻¹ on the surface.

The synthetic goethite used was prepared as was specimen 1(c) of ref. 3, and, like that specimen, consisted of thin laths with the (100) faces predominant, typically measuring 150 nm in the [001] direction, 30 nm wide and 10 nm thick. The calculated area of the (100) faces is 45 m² g⁻¹, with edge planes contributing about 15 m² g⁻¹.

The goethite structure (Fig. 2) can be regarded as being built from strips of condensed Fe(O, OH) octahedra, each

Fig. 2 Plan (a) and section (b) of the (100) face of goethite (after Bragg and Claringbull⁶).

strip being two octahedra wide. The strips, which are seen in plan in Fig. 2a, and in section in Fig. 2b, share O^{2-} ions along their edges to give an open structure in which the gaps between the strips are bridged by hydrogen bonds (dashes in Fig. 2b) involving OH groups shared between three Fe^{3+} ions. These bulk hydroxyls absorb at $3,145\text{ cm}^{-1}$. The same hydroxyls (labelled B in Fig. 2) are also exposed on the (100) surface together with two new types of hydroxyls (labelled A and C) which arise from protonation of the oxide ions along the edges of the strips. Of these surface hydroxyls,

types B and C cannot form hydrogen bonds within the surface, since all adjacent hydroxyls are coordinated to a common Fe^{3+} ion, but type A hydroxyls, each coordinated to only one Fe^{3+} , can form bonds 3 \AA long with each other.

In the spectra of films of goethite examined *in vacuo* (Fig. 3a) type A hydroxyls absorb at $3,486\text{ cm}^{-1}$ and the non-bonded hydroxyls absorb at $3,660\text{ cm}^{-1}$. These surface hydroxyls are readily converted to OD, absorbing at $2,700\text{ cm}^{-1}$ and $2,581\text{ cm}^{-1}$, by brief (1 min) treatment with D_2O , and they interact with adsorbed water when the films are exposed to air, as shown by broadening and displacement of the absorption bands.

Goethite that had been treated with $200\text{ }\mu\text{mol per g H}_3\text{PO}_4$ or NaH_2PO_4 before preparing films showed no absorption due to type A hydroxyls (Fig. 3b), thus confirming the hypothesis of Atkinson *et al.*⁴ that phosphate replaces these hydroxyls, forming bridges between adjacent Fe^{3+} . The spectra also demonstrate an interaction between phosphate and B or C type hydroxyls, resulting in new bands appearing at $3,671\text{ cm}^{-1}$ and $3,646\text{ cm}^{-1}$. This could represent the effect of a hydrogen bond between surface $(FeO)_2PO\cdot OH$ groups, acting as proton donors, and type C hydroxyls. These and other reactions of surface hydroxyl groups on hydroxides are being actively investigated.

We thank Dr W. J. McHardy for electron microscopy and Dr P. D. G. Cradwick for calculating OH-OH separations in gibbsite.

Gravitational charge, hadron hydrodynamics and Gödelised hadrons

I discuss here the consistency of approach which is not immediately apparent when current approaches to particle physics are compared. The parton model, *f* gravity and the hydrodynamical model of multiple particle production in high energy hadron collisions complement each other in remarkable ways and point to a useful general formalism for particle physics problems in such diverse applications as mass spectra through collisions to the first picoseconds of the Universe according to the big-bang theory.

Motz has obtained an expression for gravitational "charge" in the interior of fundamental particles based on the Weyl theory of gauge invariance¹ and on the Schwinger (actually Bohr-Sommerfeld) quantisation procedure² which implies a value for the gravitational constant of $\sim 1.8 \times 10^{31}$ (c.g.s. units) within a proton (or any hadron). Bakesigaki and Inomata³ have derived a value of $G \sim 1.2 \times 10^{32}$ from the strong *f*-gravity theory⁴ and a model of hadrons as de Sitter spacetimes possessing rotational degrees of freedom (relativistic "rotators")⁵ by obtaining a mass formula for hadrons

under the assumption of conformal $SO(4, 2)$ symmetry (invariance) being broken into the $SO(4, 1)$ symmetry group, the masses then corresponding to the energy levels specified by the angular momentum quantum number J .

What other sort of relativistic rotator is consistent with the existence of such large values of the gravitational constant under a gravitational charge hypothesis applied to hadronic matter (strongly interacting fundamental particles)? The simplest models should always be considered first, so I will look for classical phenomena which may still be useful for qualitative description in the quantum domain of the hadrons. The Landau hydrodynamical-thermodynamical fluid description of multiparticle production^{6,7} has recently been reconsidered with some success^{8,9}. So it seems useful to seek a fluid description, and just look at the proton as an infinitely bootstrapped¹⁰ hadron ground state. Another semiclassical approach has involved the use of the cosmological constant in the Einstein equations as the inverse square Compton wavelength of the f^2 -meson and interpreting the meson spectrum as that of an oscillator, thereby coming within half a pion mass of the proton's mass for the ground state of a hadron¹¹. I note also that the parton model of hadrons containing an almost infinite number of almost light-like particles¹² lends itself easily to a statistical-fluid description of the hadron in terms of its constituents. So I conclude that it is useful to examine a fluid description of the hadrons in which the cosmological constant also may have meaning.

One possibility is Gödel's universe¹³. To examine this I work with Gödel's spacetime line element in the form $ds^2 = (dx_0 + \exp(ax_1) dx_2)^2 - dx_1^2 - (\frac{1}{2}) \exp(2ax_1) dx_2^2 - dx_3^2$, where a is related to the rotation velocity w and the speed of light, c by $w = (ac/2)^{1/2}$ (ref. 14). The Einstein field equations for such a line element then imply that the density u and pressure p of the matter are related by $p = u = a^2$ (in geometrised units), implying unusual properties for such matter¹⁵. An alternative interpretation of the Gödel solution would constrain the fluid to $p = 0$, $u = -\Lambda/4\pi$, where Λ is the cosmological constant, and $\Lambda = -a^2/2$ (ref. 14).

So there are two possible approaches. In the first case, one fixes the field of the proton near its surface from application of the Kerr-Newman metric in an f -gravity form¹⁶, thereby fixing the curvature for the density u and then matching that curvature *a priori* to $u = a^2$ in the Gödel solution. The second case would involve self-consistent use of the relation $u = a^2$ entirely within the Gödel solution but that would make no reference to f gravity and allow no connection of possible exterior and interior solutions to the field equations $G_{ab} = -k T_{ab}$ for a fluid hadron, which is a part of the motivation for this work. I use the former.

Let the rotation w be given by the usual relation of angular momentum L to moment of inertia I ($w = L/I$) and let $I = Q_p MR^2$ where M is the particle mass, R is its radius and Q_p is the gravitational charge. Inserting the parameters for the proton of $M = 1.6 \times 10^{-24} g_m$, $L = \hbar/2$ ($\hbar =$ Dirac's constant), and $R \sim 10^{-13}$ cm, using the Kerr-Newman curvature from the components of the Riemann tensor in the equatorial plane ($R_{\theta\phi\theta\phi} \sim GM/c^2 r^3$), $u \sim 1.1 \times 10^{-12}$ cm², and further augmenting the gravitational effect of the mass implied by the ultrarelativistic 'equation of state' $p = u$ (that is, doubling the mass), we find $Q_p \sim 3 \times 10^{17}$. Applying the charge relation of Motz² ($Q = G^{1/2}$) we find $G = Q_p^2 \sim 9 \times 10^{34}$. This is a larger value of G than found by others^{1,2} but it does augment their impression of extremely large values of G within hadrons.

The values may be brought into agreement by detailed consideration of the charge distribution in the particle¹⁷ or its mass distribution (these distributions being possibly of equal value here because an application of the parton model with a vector gluon interaction between partons has shown

that the two distributions are related and may be identical¹⁸), by perhaps allowing a density distribution $u \sim u_0 \exp(-x_1/c)/x_1$, where l is a scale length. That is not unreasonable since it is the coupling of the field and its source which produces gravitation and this source distribution has the structure of the Yukawa field. Peak's consideration of the relation of strong gravity and the Yukawa potential, indeed, derives an equation which implies such a form of u (ref. 19). Such a distribution yields a decreased requirement on Q_p in the moment of inertia, implying a value of $G \sim 3 \times 10^{32}$. I have found that the Einstein tensor for the inhomogeneous Gödel model calculated from the distribution $u_0 \exp(-x_1/c)/x_1$, with $a = a(x_1)$, contains non-zero G_{12} terms corresponding to stresses in the matter. These determine Maclaurin spheroids which may be matched to the quadrupole moment and angular momentum relation in the Kerr-Newman solution and its axis-symmetric null surfaces.

Using the cosmological constant instead gives the same results. The only problem, that of consistency with present work in particle physics, involves the $p = 0$ equation, but hadron models with such a constraint are under construction by a group at Massachusetts Institute of Technology and it has been shown that a hadron gas under conditions of compaction of the early Universe similar to that of the maximum temperature ($T_m = 160$ MeV) hydrodynamical model²⁰ may obey an equation of state such that u is so much greater than p that p may be set equal to zero by comparison with u (ref. 21).

The above consideration is worth noting because there now exists the formalism of the tilted universe in cosmology²² which is immediately adaptable to the $f - g$ gravity theory by adding the coupling terms in the field equations to the cosmological equations⁴, with or without cosmological constant (with or without altered constraints on the equation of state such as $p = 0$). But the tilted frames are specified by the same coordinate transformations which specify the infinite momentum frames of the parton model¹²; so either way, a complete formalism now exists to do the complete physics of the first picoseconds of the big-bang origin of the universe, including gravitation, hydrodynamics and thermodynamics, and particle physics under the constraints of completely and consistently specified models.

There is, in conclusion, a remarkable consistency in these new gravitationally/hydrodynamically oriented approaches to the structure of the fundamental particles and a much greater range of applicability (from hadrons to 3C295) than has been attempted.

I thank J. J. Burton, L. Motz, G. Frye, and F. Cooper for criticisms.

BIOLOGICAL SCIENCES

Specific recognition of the isolated R17 replicase initiator region by R17 coat protein

Coat proteins from the RNA bacteriophages of groups I (R17, MS2, f2) and III (Q β) specifically bind to their homologous RNAs and serve as translational repressors of replicase synthesis¹. In the case of R17, a fragment of the genome which is protected by coat protein from T₁ RNase digestion² contains not only the ribosome binding site of the replicase cistron³, but also the preceding intercistronic region and 23 nucleotides (including the terminator triplets) from the coat gene⁴. Physical studies described in the previous papers^{5,6} suggest that the structure of this isolated R17 fragment consists of two hairpin loops joined by a single-stranded region; the coat protein binds in such a way as to alter the behaviour of only one of these helical regions⁵, that which contains the initiation site for the replicase gene. Here I show that this portion of the fragment alone is sufficient for recognition by the coat protein.

Isolated protein synthesis initiator regions from R17 RNA⁷ provide a convenient source of the 3' terminal one-third of the coat protein-protected fragment (helix *b* of Fig. 1, ref. 5). Such ribosome binding site preparations contain a mixture of the beginnings of the three R17 genes, each present in several size variants as illustrated in Fig. 1.

Table 1 and Fig. 2 show that the replicase initiator region can be both selectively and efficiently bound to Millipore filters by R17 coat protein. If the mixture of coat protein

and ribosome binding sites is treated with T₁ RNase before filtration, only those oligonucleotides which are at least partially contained in helix *b* (Fig. 1, ref. 5) are protected. Interestingly, Q β coat protein shows some affinity for the R17 replicase initiator region suggesting that it recognises a structurally similar site in its own RNA; the fact that the binding is less efficient and abolished by T₁ RNase probably explains why no protection of whole R17 RNA by Q β coat protein was previously observed².

The capacity of R17 coat protein to recognise the replicase

Fig. 2 T₁ RNase fingerprints of R17 initiator fragments (a) before incubation with, and (b) trapped on Millipore filter by R17 coat protein. Data is from experiment 1 of Table 1. Spots were identified by subsequent analysis as: 5R-AUUACCCAUG, 7R-AAACAUG, 4R-ACAACAAAG and 10R-UCG from the replicase site; 6A-ACCUAUG, 3A-AUCCUAG, and 1AC-UUUG from the A site; 9C-CAUG, 2C-CUUCUAACUUU, and 1AC-UUUG from the coat protein initiator region.

R17 protein synthesis initiator regions were prepared by ribosome protection, isolated and characterised as described in ref. 7 and Fig. 2a. Reaction mixtures contained in 60 μl of TMK buffer (0.1 M Tris-HCl, pH 7.5; 0.01 M Mg acetate; 0.08 M KCl); 32 μg of isolated R17 ribosome binding sites (of which only 1–2% are the radioactive sites, the remainder being rRNA and tRNA fragments⁷) and 7.6 μg freshly prepared R17 or Q β coat protein⁸, or bovine serum albumin (BSA). After 10 min at 0° C, T₁ RNase at 0.1 mg ml⁻¹ was added as indicated and incubation continued for 30 min at 25° C. Samples were filtered through HA Millipore filters (24 mm) and the RNA extracted as described in ref. 2. Final preparations were analysed by two-dimensional T₁ fingerprints (Fig. 2b) and the above oligonucleotides counted and analysed. In both experiments, controls with BSA rather than coat protein, gave no detectible spots on the fingerprints. The oligonucleotides are identified in Fig. 2. Ratios of the sites were calculated from the relative yields of the underlined oligonucleotides, which contain the three initiator AUGs. The % replicase site bound was calculated from the fraction of replicase sites in the counts originally trapped on the filter. Spots containing less than 20 c.p.m. total were not detected and are indicated by —; spots were not counted where no value appears.

TABLE 2 Rebinding of coat protein-protected fragments

	Addition at		Filter at
	0 min	10 min	20 min

	Coat	T ₁ RNase	2616
	T ₁ RNase	Coat	60
	—	—	25

The 59- and 29-nucleotide fragments were prepared as described in ref. 5; after elution from the gel they were characterized by T₁ fingerprint analysis to be approximately 90% pure. Rebinding reactions were performed in 50 μl of TMK buffer at 25° C containing (as indicated): 3.8 μg freshly prepared R17 coat protein⁸, 1.4 μg of the 59-nucleotide or 0.7 μg of the 29-nucleotide fragment (a 4:1 molar ratio of coat protein to RNA), and 0.05 mg ml⁻¹ T₁ RNase. After dilution with 1 ml of TMK buffer, the samples were filtered with two 1 ml rinses through HA Millipore filters and counted in toluene scintillation fluid.

initiator region, as opposed to the 59-nucleotide RNA segment studied in refs 5 and 6, can also be examined directly since a T₁ digest of the coat protein R17-RNA complex yields both fragments (see Fig. 1, ref. 5). Table 2 shows that the 29- and 59-nucleotide fragments are retained on a Millipore filter by coat protein with comparable efficiency.

Thus it may be concluded that the 23 nucleotides at the

3' terminus of the 59-nucleotide fragment isolated from the R17 RNA-coat protein complex are sufficient for recognition by the protein. As originally suggested by Bernardi and Spahr², helix *a* (the coat cistron terminator region) most likely remains attached because of its great stability and resistance to RNase.

Must the R17 replicase initiator region assume a helical form to be recognised by coat protein? Its component T₁ oligonucleotides, which contain the sequence from the turn of hairpin *b* intact in oligonucleotide 5R (Fig. 1), are not efficiently rebound (Table 2); and studies presented in accompanying papers^{5,6} indicate that helix is formed by this portion of the 59-nucleotide fragment under physiological conditions. Formation of a secondary structure which sequesters the initiator AUG could explain the inability of *E. coli* ribosomes to recognise the isolated replicase initiation site efficiently⁷. In the intact R17 RNA, on the other hand, the region may well assume one of several alternative configurations⁸: an extended form, in which the initiator AUG may become available for ribosome binding after translation of an early portion of the coat gene; or the helix, which is subject to coat protein recognition and translational repression.

I thank J. Gralla and T. Yamane for many helpful discussions. This work was supported by a grant from the National Institutes of Health.

High resolution proton NMR study of an isolated fragment of R17 bacteriophage mRNA

HIGH resolution nuclear magnetic resonance (NMR) spectra of the hydrogen-bonded protons in helical regions of nucleic acids are an informative monitor of the base pairing¹. Studies of about 10 purified tRNAs and of model systems have shown that the ring NH protons of uracil and guanine, when involved in Watson-Crick base pairing, give resonances between -15 and -11 p.p.m. downfield from DSS^{1,2}. Since there is only one such proton in each base pair, the intensity in this spectral region is a direct measure of the number of base pairs. Simple rules have been derived to predict the NMR spectra originating from these protons on the basis of ring currents from the adjacent bases and for tRNA the comparison between predicted and observed spectra has strongly supported the clover leaf model of base pairing. In addition, ring current shifts from bases adjacent to the helical region provided information about the structure at the end of the helix. Here we apply this approach to the secondary structure of the R17 fragment discussed in the preceding paper³. We prepared 0.5 mg of the R17 fragment according to a somewhat modified method of Bernardi and Spahr⁴, and measured the NMR spectrum of a 25 μ l sample.

Figure 1 shows the 300 MHz high resolution proton NMR spectra of the fragment at 26° C and 40° C, obtained with a Varian HR300 spectrometer after accumulation for ~7 and ~13 h, respectively. These spectra, with resonances between -15 and -11 p.p.m., are similar to those obtained^{1,2} from other nucleic acid molecules of comparable size (for example, tRNAs) although these lines are broader. Assuming that the peak at either -11.6 p.p.m. or at -14.3 p.p.m. represents one proton, the spectrum at 26° C has a total intensity corresponding to ~16 protons, in agreement with the number of base pairs expected from the structure shown in Fig. 1 of the previous paper³. Note that GU does not, in our experience, contribute a resonance in the region between -15 and -11 p.p.m.⁵

Upon raising the temperature from 26° C to 40° C, the overall form of the spectrum changes drastically. There is an appreciable intensity reduction below -13.0 p.p.m. and the line at -11.6 p.p.m. has disappeared. After maintaining the sample for many hours at 40° C the resonances subsequently obtained at 26° C were broadened, presumably due to aggregation of the sample at this high concentration. So we could not make a direct intensity comparison between the 26° C and 40° C spectra. At 40° C the intensity in the low field part of the spectrum relative to the high field part is much lower than in the 26° C spectrum. On the basis of internally consistent intensities in the 40° C spectrum its integrated intensity corresponds to ~eight protons. Loss of about eight resonances is consistent, within experimental error, with the melting of either the *a* or the *b* region of

the structure proposed for the mRNA fragment (Fig. 1 of ref. 3). To interpret the results in more detail the spectra expected for the two proposed helices were calculated on the basis of the ring current shift contributions from nearest neighbours with the results given by the stick diagram at the bottom of Fig. 1.

The melting observed by NMR can be ascribed to a certain helical region only if at least one resonance can be assigned to the hydrogen-bonded NH proton of a particular base pair in that helical region. Since the accuracy of the calculation is no better than ~0.3 p.p.m.^{1,2} it is necessary to have a resonance which is separated by at least this distance from the rest of the spectrum before it can be unambiguously identified merely by comparing the calculated spectrum with the observed. Fortunately, such a line does appear near -11.6 p.p.m., corresponding to the GC43 (GC base pair involving nucleotide number 43 from the 5' end) and this is the only resonance calculated to be at fields higher than ~12.0 p.p.m. This assignment is independent of whether we assume that A44 is looped out so that GC45 stacks on GC43 giving a calculated position of -11.8 p.p.m. or that A44 is stacked between pairs 43 and 45 giving -11.4 p.p.m. for GC43. Although we cannot distinguish between these two possibilities now, the observed position of the GC43 resonance requires that one of these two conformations exists. The disappearance of the resonance at -11.6 p.p.m. in going from 26° C to 40° C suggests that resonances of the *b* helix are broadening in this temperature range. This conclusion is corroborated by the simultaneous intensity loss in the rest of the spectrum which coincides rather well with the reso-

FIG. 1 The 300 MHz NMR spectra of the ring NH hydrogen-bonded protons of the R17 fragment at 26° C and 40° C. Positions are given in parts per million (p.p.m.) downfield from a DSS (2,2-dimethyl-2-silapentane-5-sulphonate) standard. The stick diagram at the bottom of the figure depicts the spectrum calculated for the secondary structure given in Fig. 1 of the previous paper³. The dashed lines correspond to the *a* helix which contains the termination codon for the coat protein gene, the solid lines to the *b* helix which contains the initiator codon for the replicase gene. Concentrations in the solution were: RNA fragment ~0.5 mM; NaCl, 50 mM; MgCl₂, 8 mM; ammonium cacodylate, 10 mM. The total sample volume was 0.025 ml in an approximately spherical NMR microcell. The R17 RNA fragment was prepared as described in Fig. 1, ref. 3. Examination of aliquots of the sample by polyacrylamide gel electrophoresis and by T₁ and pancreatic RNase fingerprinting showed it to be more than 95% pure.

nances expected from the other base pairs in the *b* helix. In particular, the loss of intensity observed around -13.1 p.p.m. is understandable if we include base pairs GC45 and GC46 in the *b* helix; without these two pairs no intensity decrease would be expected in this spectral region from the other five base pairs of helix *b*.

The NMR results on the R17 RNA fragment presented here support the interpretation of the melting behaviour given in the preceding paper³ in that the *b* helix is the first to melt, and in this way support the rules for thermodynamic stability developed to predict the secondary structure of RNAs⁷.

The results indicate that the AUG initiation triplet of the R17 replicase gene is buried in a base-paired region in this particular fragment. The combination of relaxation kinetics and NMR shows that while the fragment is predominantly base paired under physiological conditions, there is still a finite possibility of finding the helix open. Raising the temperature above 40°C would increase the fraction of time that helix *b* is open and in this way it might be possible to observe changes in the biological function of this fragment, that is initiation and translation, which could be correlated with changes in the helix-to-coil equilibrium of the helix containing the AUG initiator codon.

Effect of camptothecin on simian virus 40 DNA

THE alkaloid camptothecin has been shown to be a potent, rapidly acting inhibitor of RNA and DNA synthesis in eukaryotic cells¹⁻⁵. The drug is selectively active against high molecular weight nuclear RNA synthesis²⁻⁵, having no effect on mitochondrial⁶ or 4-5S RNA synthesis^{2,5}. Its effect on RNA synthesis is rapidly reversible^{1-3,5}. In addition, it has been shown that camptothecin induces alkali-labile links in DNA^{1,7-9} which are rapidly reversed by removal of the drug⁹. It was suggested that this action on DNA is responsible for the effect of the drug on RNA synthesis⁵.

Here we describe the effect of camptothecin on simian virus 40 (SV40) DNA. These molecules normally exist as either covalently closed superhelical double-stranded circles (component I) or relaxed circles containing single-strand scissions (component II). Introduction of even one single-strand break in component I molecules can be easily assayed because of the drastic change in sedimentation coefficient

(from 53S for component I to 16-18S for component II) seen during centrifugation in alkaline gradients. Such analysis shows the major effect of camptothecin treatment to be the introduction of one single-strand break or alkali-labile region per component I molecule affected.

To study the effect of camptothecin on SV40 DNA, labelled viral DNA from infected drug-treated cells was analysed by

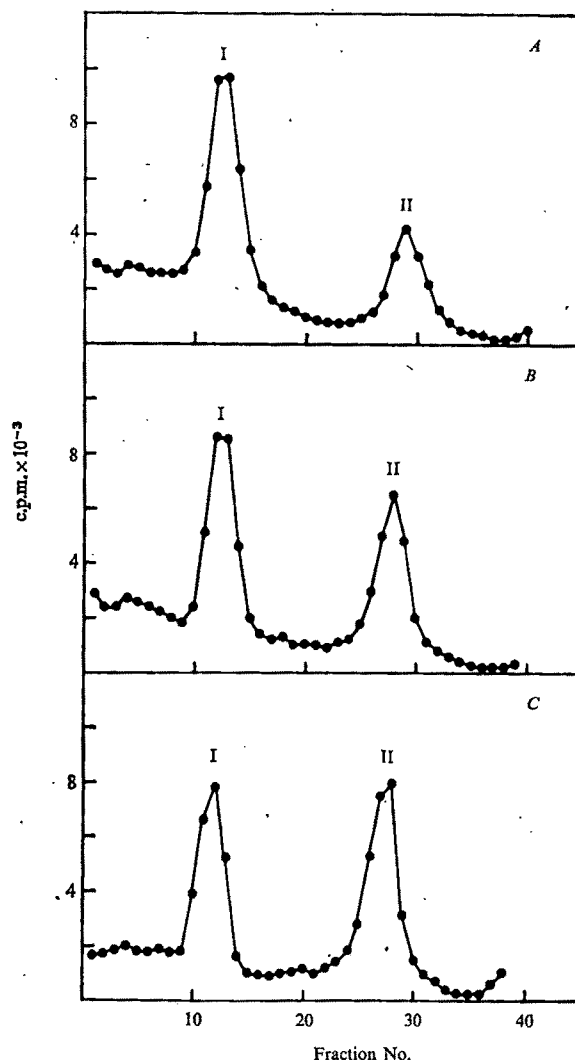

Fig. 1 Velocity sedimentation in alkaline CsCl of viral DNA extracted from cells treated with camptothecin. Confluent monolayers of Vero cells, grown in 60 mm Petri plates in Dulbecco-Vogt medium with 10% Colorado calf serum, were infected with SV40 (small plaque strain) at a multiplicity of approximately 2 plaque-forming units (PFU) per cell. The virus was allowed to adsorb to the cells for 3 h at 37°C , at which time the inoculum was replaced with medium and the incubation continued at 37°C . Fresh medium containing $20\ \mu\text{Ci ml}^{-1}$ ^3H -thymidine (Mallinckrodt, $14.6\ \text{Ci mM}^{-1}$) was added at 45 h after infection, and the incubation was continued 3 h, at which time viral DNA from one plate (A) was immediately extracted by the method of Hirt¹². Other plates were treated for 30 min at 37°C with $10\ \mu\text{g ml}^{-1}$ camptothecin (B) or $100\ \mu\text{g ml}^{-1}$ camptothecin (C) in fresh medium, followed by Hirt extraction using lysing buffer containing $5\ \mu\text{g ml}^{-1}$ camptothecin. Aliquots (0.1 ml) of the Hirt supernatants were layered on 3 ml CsCl ($\rho = 1.52$) containing $0.1\ \text{M K}_2\text{HPO}_4$ (pH 12.9), and centrifuged at 15°C for 80 min in an SW 50.1 rotor at 44,000 r.p.m. The tubes were punctured and fractions were collected as described¹⁴ on 22.8 cm diameter, segmented Whatman GF/A filter discs which were dried, then washed in a Büchner funnel with 6% trichloroacetic acid and absolute ethanol. Segments containing individual fractions were then pulled off with forceps, dried in scintillation vials, and counted in toluene-Liquiflour scintillation fluid. Sedimentation is from right to left.

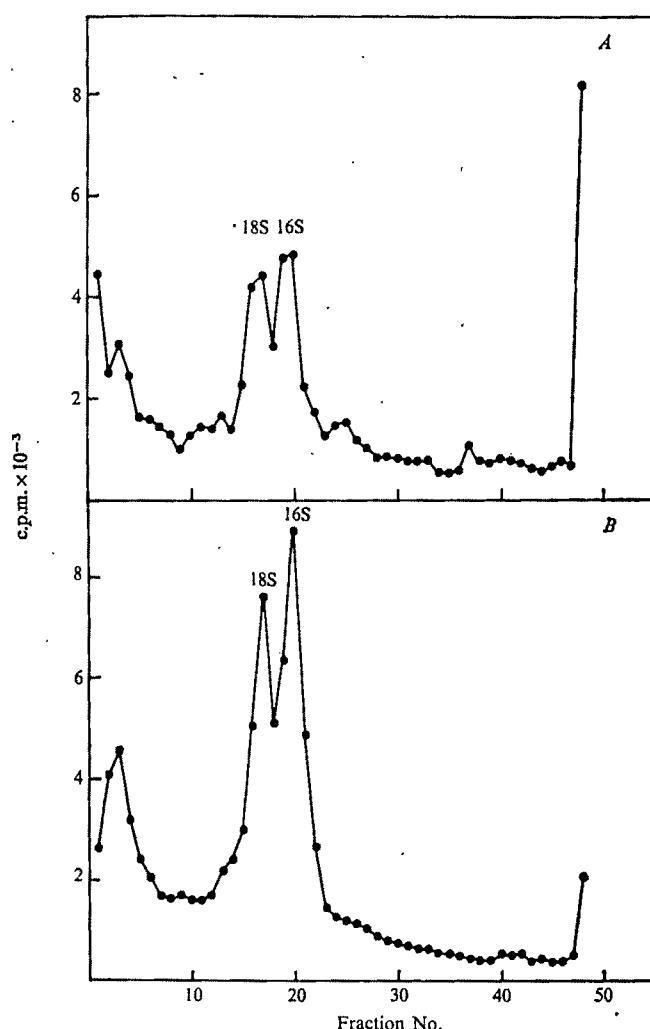

FIG. 2 Velocity sedimentation in alkaline sucrose of viral DNA extracted from camptothecin-treated cells. Aliquots (0.2 ml) of Hirt supernatants of the untreated cells (A) or the cells treated for 30 min with 100 µg ml⁻¹ camptothecin (B) (see legend to Fig. 1) were layered on 11 ml 10–30% sucrose gradients containing 0.3 M NaOH, 0.7 M NaCl, 0.001 M EDTA. Centrifugation was for 16.5 h at 10° C in an SW41 rotor at 40,000 r.p.m. Fractions were collected on GF/B filters (see legend to Fig. 1). Sedimentation is from right to left.

alkaline caesium chloride centrifugation. As shown in Fig. 1A, viral DNA sediments as two bands in such gradients, component I at 53S and component II at 16–18S. Component I comprises the majority of the viral DNA molecules in normal conditions, with component II arising mainly from the random introduction of one single-strand break per component I molecule¹⁰.

When infected cells making viral DNA are treated with camptothecin for a short period of time, some of the component I molecules are converted to component II. Treatment of cells containing labelled viral DNA for 30 min with 10 µg ml⁻¹ camptothecin (Fig. 1B) produces some conversion, an effect which can be heightened by increasing the concentration of camptothecin to 100 µg ml⁻¹ (Figure 1C). As shown in Table 1, up to one-third of the component I molecules are converted to component II in these conditions. (Incubation without camptothecin causes no appreciable change in the distribution of components I and II.)

To characterise the mode of action of camptothecin further, viral DNA from treated and control cultures was centrifuged through alkaline sucrose gradients in conditions which allow the partial resolution of the separated circular (18S) and linear (16S) strands of component II (Fig. 2). Consistent

TABLE 1 Component I molecules converted to component II

Camptothecin treatment	% Component I	% Component II	% Component I converted to component II
None	67	33	—
10 µg ml ⁻¹ , 30 min	54	46	19
100 µg ml ⁻¹ , 30 min	44	56	34

Areas in Fig. 1 were determined under component I and component II peaks by the method of Girard, *et al.*¹². Values are expressed as % of total component I plus component II.

with the results in Fig. 1, there is an increase in radioactivity in both the 18S and 16S peaks in the camptothecin-treated sample. (The amount of component I cannot be estimated as in these conditions some of the molecules pellet.) Quantita-

FIG. 3 Velocity sedimentation in alkaline gradients of cellular DNA from camptothecin-treated cells. Vero cells were labelled with 10 µCi ml⁻¹ ³H-thymidine for the 12 h before infection. At 48 h post-infection, cultures were treated with 100 µg ml⁻¹ camptothecin for 30 min, removed from the plates with trypsin-EDTA, and layered on alkaline sucrose gradients (A and B), as described by Abelson and Penman⁹. The 10 ml gradients containing 15–30% sucrose in 0.2 M NaOH, 1 M NaCl, 0.01 M EDTA, were prepared on top of a 0.5 ml cushion of 35% CsCl in the same buffer. Then 0.5 ml of lysing solution (1% Sarkosyl; 0.2 M NaOH, 5% sucrose) was layered on top of the gradient, followed by the suspension of whole cells. Parallel cultures were extracted by the method of Hirt¹². Aliquots (0.2 ml) of the Hirt supernatants were layered on the same type of gradients (C and D) or on alkaline CsCl (E and F). The alkaline sucrose gradients were centrifuged for 2 h at 40,000 r.p.m. in an SW 41 rotor at 24° C. Centrifugation of the alkaline CsCl was for 80 min at 44,000 r.p.m. in an SW 50.1 rotor at 15° C. The positions of the SV40 component I and II DNA added as external markers are indicated. A, C and E, DNA from infected cells; B, D and F, DNA from mock-infected cells. ●, camptothecin-treated cells; ○, untreated cells. Fractions were collected from the top using the Buchler Auto Densi-Flow (A and B), or from the bottom by puncturing the tube (C–F), then assayed on GF/B (A–D) or GF/A (E and F) filters (see legend to Fig. 1). In gradients displaying the centrifugation of aliquots of Hirt supernatants (C–F), the axes were corrected to represent the radioactivity present in the entire Hirt supernatant. Sedimentation is from right to left in all panels.

tion of the approximate areas under the 16S and 18S peaks demonstrates that they are in the same relative proportions in the camptothecin-treated sample as in the untreated control. This would not have resulted had the affected molecules received either a double-strand break or two single-strand breaks in opposite strands. In either case a preponderance of 16S linear molecules would have been observed.

Furthermore, there are no new lower molecular weight discrete species discernable due to drug treatment, as would be expected if the drug caused two or more breaks at specific sites on a single strand. It is possible, however, that the single-strand breaks caused by the drug are randomly located on the viral DNA. If this were the case, the result of multiple breaks would be relatively small increases in the ratio of 16S to 18S DNA, and in the heterodisperse, lower molecular weight background. We would not detect these changes in our experiments.

It might be argued that cellular DNA, which is broken or rendered alkali-labile by camptothecin treatment^{1,7-9}, would appear in the extracts, complicating our results. The patterns shown in Figs 1 and 2 give no indication that pulse-labelled cellular DNA, synthesised after infection, is extracted and sediments near viral DNA in alkaline conditions. We have also tested the effect of the drug on cellular DNA synthesised before the infection. The results presented in Fig. 3 show that pre-labelled cellular DNA is broken (or rendered alkali-labile) by the drug, and sediments in alkali only slightly faster than viral DNA (Fig. 3, A and B), but is removed or repaired during the extraction (Fig. 3, C-F).

We have shown that the principal change in SV40 DNA caused by camptothecin is the production of one single-strand break or alkali-labile region in the molecule. It is possible that additional breaks may occur at random locations in the molecule. These experiments with closed circular DNA constitute the first direct indication that the drug affects only one DNA strand, rather than inducing double-stranded alkali-labile regions.

It has still to be determined if the specificity of the camptothecin effect on SV40 DNA is due to the drug's preference for a particular sequence of nucleotides, similar to the mode of action of restriction endonucleases¹¹, or if the drug can cause a scission at any site on the molecule. In addition, it is still unclear whether the drug's effect on SV40 DNA is the induction of single-strand breaks or alkali-labile links, as has been suggested for cellular DNA by Abelson and Penman⁹. Further experiments are under way to determine the mechanism of action of camptothecin on SV40 DNA.

This research was supported by a contract from the Special Virus Cancer Program of the National Cancer Institute. We thank Charles Motley and James Gragg for technical assistance, and Dr Harry B. Wood, jun., Drug Development Branch, National Cancer Institute for providing the camptothecin (sodium salt, NSC-100880).

Localisation of Monocyte Binding Site of Human Immunoglobulin G

THE binding of IgG to macrophages is thought to be important in both the afferent and efferent limbs of the immune response¹⁻³. Berken and Benacerraf⁴ studied the properties of guinea pig IgG2 antibodies cytophilic for macrophages and concluded that the binding site was in the Fc region. Similarly Lo Buglio *et al.*⁵ and Abramson *et al.*⁶ inhibited with isolated Fc fragment the binding of human monocytes to red cells coated with anti-D. Abramson *et al.*⁶ also studied the inhibitory activity of various fragments obtained by peptic digestion of IgG. The F(ab')₂ fragment was slightly inhibitory, unlike Fab fragment, and the authors suggested that the binding site was in the N-terminal portion of the Fc fragment (now known as the C_H2 region). Huber and Fudenberg⁷ reached similar conclusions following experiments in which F(ab')₂ fragments of anti-D antibodies were attached to red blood cells and produced rosettes with human monocytes, although the possibility of contaminating IgG could not be eliminated. In contrast, MacLennan *et al.*⁸ were unable to inhibit neutrophil phagocytosis of sensitised bacteria with immune complexes of antigen and the F_{ab} fragment of rabbit IgG. Since the F_{ab} fragment includes the Fab and C_H2 regions but lacks the C_H3 region this suggests that the latter may be the site of neutrophil binding. Furthermore, Yasmien *et al.*⁹, working with a

Fig. 1 Percentage inhibition of monocyte rosette formation obtained with different molar concentrations of IgG, various subfragments of IgG and human serum albumin. % Inhibition was obtained from the formula:

$$100 - \left[\frac{\frac{\text{Number of rosetting cells in test}}{\text{Number of monocytes in test}}}{\frac{\text{Number of rosetting cells in control}}{\text{Number of monocytes in control}}} \times 100 \right]$$

where the control consisted of cells and medium only. The curves represent values obtained in a single experiment. Similar values were obtained in a duplicate experiment. ○, Intact IgG; ●, pFc' fragment; ■, Fc fragment; ♦, Fab fragment; □, human serum albumin.

heterologous system (human immunoglobulin G and guinea pig macrophages) have presented evidence that macrophage binding is a property of the C_H3 region of the molecule. In view of these conflicting reports we have investigated the possible role of the C_H3 region of human IgG in binding to homologous monocytes.

Human monocytes were prepared essentially as described by Hay *et al.*¹⁰ and resuspended to a final concentration of 4×10^5 cells ml⁻¹ in medium lacking foetal calf serum (FCS). The cell suspension (0.5 ml = 2×10^5 monocytes) was distributed in equal quantities into chambers consisting of lucite rings affixed to 22 mm square glass coverslips. The chambers were placed in a humidified airtight box fitted with inlet and outlet tubes. The latter were used to introduce an 8% CO₂-air mixture into the box. After incubation for 1 h at 37° C each chamber was washed once with medium lacking FCS to remove cells not adhering to the walls of the chamber.

For the inhibition experiments Fc and Fab fragments of pooled human IgG (obtained from Kabi A. B., Stockholm) were prepared by papain digestion¹¹ and isolated by ion-exchange chromatography¹². The pFc' fragment of pooled IgG (i.e., the C_H3 region) was prepared by pepsin digestion and isolated by Sephadex G-150 gel filtration¹³. Similar series of different concentrations of each fragment were prepared (assuming E₁^{1%}_{cm} 280 nm. of 14.6), and 0.5 ml of each preparation was added to a chamber. Every sample was duplicated and a control consisting of 0.5 ml of medium (without FCS) was also included. The chambers were flushed with 8% CO₂-air and incubated at 37° C for 1 h. The chambers were washed twice with medium and 0.5 ml of a 0.5% suspension of human red cells, previously coated with incomplete anti-D, was added to each. After flushing again with 8% CO₂-air the chambers were incubated at 37° C for 30 min and finally at 4° C for a further 30 min. Each chamber was then filled with medium, covered with a microscope slide and inverted to bring the coverslip uppermost. The degree of rosette formation was then assessed by phase contrast microscopy. Approximately 100 cells were counted in each chamber and monocytes binding two or more red cells were counted as rosettes.

Figure 1 shows the percentage inhibition of monocyte rosette formation obtained in a single experiment with different concentrations of pooled human IgG, Fc, Fab and pFc' subfragments of IgG and human serum albumin. All inhibitors were studied over the concentration range 0.02–1.0 mg ml⁻¹, but since the Fc and Fab fragments represent only one third, and the pFc' fragment one sixth, of the intact IgG molecule, the data in Fig. 1 are expressed on a molar basis. At concentrations between 20 and 200 nmol ml⁻¹ of each inhibitor the pFc' fragment, the Fc fragment and whole IgG showed levels of inhibition between 80% and 100% whereas HSA and Fab fragments showed values of less than 20%. Similar results were obtained over the same concentration range when the same protein preparations were tested in a second study. The percentage inhibition obtained with the different proteins and fragments (used at a concentration of 1 mg ml⁻¹, which discriminated readily between Fc and

Fig. 2 Percentage inhibition of monocyte rosette formation obtained with preparations of pFc' fragment from, a, human IgG1; b, IgG2; c, IgG3; and, d, IgG4 myeloma proteins. Inhibitor proteins were prepared as previously described¹⁴ and detailed chemical characterisation is presented elsewhere¹⁵. The results of two separate experiments are plotted.

Fab fragments) in these and other replicate experiments are shown in Table 1. These results suggest that the binding site for homologous macrophage fixation is located in the pFc' region of the IgG molecule, as was also recently reported for heterologous interactions⁹.

In additional experiments inhibition of rosette formation was investigated with pFc' fragments isolated from all four subclasses of human IgG. Two IgG1 myeloma proteins and single samples of IgG2, IgG3 and IgG4 myeloma proteins were digested with pepsin to yield pFc' fragments and the fragments isolated by Sephadex G-150 gel filtration¹⁴. The results of two separate inhibition experiments are shown in Fig. 2. The pFc' fragments from IgG1 and IgG3 myeloma proteins inhibited rosette formation more strongly than did

Table 1 Inhibition of Monocyte Rosette Formation by Pooled Human IgG and Various Subfragments

Inhibitor*	% Inhibition obtained in different experiments†		
IgG	100	100	100
Fc fragment	100	100	
Fab fragment	20	9	8
pFc' fragment	100	99	
Human serum albumin	30	2

Fig. 3 Schematic model of human IgG molecule showing the binding activities associated with the different homology regions.

pFc' fragments from IgG2 and IgG4 myeloma proteins. The subclass distribution observed with pFc' fragments parallels exactly the results obtained using subclass proteins^{6,10,16}. None of the preparations, however, inhibited as well as pFc' fragment from pooled IgG. A possible explanation of this observation is that there are different binding sites for the different IgG subclasses, either on the same cell or on different cells. But such an explanation conflicts with the conclusions of Huber *et al.*¹⁶, who studied the monocyte binding activity of intact subclass proteins.

The possibility that the monocyte receptor interacts with aggregated rather than native pFc' fragment was investigated in the following manner. A concentrated preparation of pFc' fragment was chromatographed on Sephadex G-150 and a fraction of the eluted peak ($S_{20,w}=2.3$) was taken directly, without any concentrating procedure, for ultracentrifugal analysis in the MSE Centriscan at 60,000 r.p.m. Monocyte rosette inhibition was assayed simultaneously on the same sample. This material, which was shown to be fully inhibitory, contained no detectable aggregates (threshold of detectability 1.5% of total protein). Furthermore radio-labelled monomeric pFc' fragment was concentrated by three different procedures (ultrafiltration, lyophilisation and polyethylene glycol) and rechromatographed on Sephadex G-150. Aggregated material, if present, represented less than 0.25% of the total counts applied to the column. We therefore conclude that the monocyte receptor probably has specificity for native IgG rather than denatured or aggregated IgG.

Our study is further evidence for Edelman's 'domain concept'^{17,18} that the homology regions of the individual peptide chains of IgG interact to form six globular units each of which has evolved to perform a distinct function. Binding sites for antigen, for the C1q component of complement and for monocytes have now been localised to separate homology regions (see Fig. 3), and the importance of each of these activities might be expected to exert strong evolutionary pressure for the conservation of each binding site.

The ultracentrifugal analysis was kindly performed by Drs D. R. Stanworth and P. Johns, University of Birmingham.

Antibody response and virus survival in cats vaccinated against feline leukaemia

We have shown that leukaemia virus can be transmitted from cat to cat by contact or aerosol¹. There is also substantial epizootiological evidence that such transmission occurs in natural conditions^{2,3}. Horizontal transmission occurs because feline leukaemia virus (FeLV) replicates not only in cells of the haematopoietic system but is also found in large amounts in respiratory and alimentary mucous membranes and is excreted in the urine⁴. It is therefore not surprising that the infection in cats is fairly common. In the City of Glasgow we found that about one third of the cats sampled had antibodies against FeLV (mean titre = 2; ref. 4). We recently examined 100 young cats from the surrounding countryside and found antibody in six (mean titre = 20). These facts indicate that vaccination would be valuable and we have evidence that it is feasible. Here we report on the use of FeLV-infected cells to produce an immune response of a high level in cats.

The antibodies being measured are directed against the virus subgroup specific glycoprotein antigens which are located on the membrane of the infected cell and on the envelope of the virus; they have the same specificity as those responsible for virus neutralisation and cell cytotoxicity (W. J., L. M., O. J., H. L., and C. H., unpublished). An indirect immunofluorescence test is used in which the target cells are living, virus-infected, feline lymphoblasts which are cultured in suspension^{4,5}.

We inoculated cats with infected cells for two main reasons. First, in the feline sarcoma virus (FeSV) system, high antibody titres have been associated with either failure of tumour induction or regression of established tumours⁶. Similar results have not been reported in feline leukaemia. We therefore tried to mimic the sarcoma situation by injecting cats with packs of fibroblasts which were actively replicating FeLV from their cell membranes. This was on the assumption that to obtain high antibody levels it might be necessary to present cell walls bearing antigen arrays to

Fig. 1 Group mean antibody responses in three groups of cats inoculated with FeLV-infected cells. Group a received 4×10^7 feline embryo (FEA) monolayer cells; group b were given 4×10^7 feline lymphoblastoid cells grown in suspension, and group c received 2×10^9 FEA cells.

TABLE 1 Type and number of cells infected with various subgroups of FeLV used to immunise cats, the peak antibody titres induced the relationship of the immune response to the establishment or persistence of virus infection

Cat	Type	Cells No.	Peak antibody titre	Duration of experiment (months)	Virus isolation after necropsy	Virus subgroups
1	FEA*	2×10^9	256	13	+	A + B
2	FEA	2×10^9	128	13	+	A + B
3	FEA†	2×10^9	32	6	+	A + B
4	FEA†	2×10^9	64	6	+	A + B
5	FEA§	2×10^9	256	6	+	A
6	FEA§	7×10^8	128	6	+	A
7	FEA§	7×10^8	64	6	+	A
8	FEA	4×10^7	128	1	0	A + B + C
9	FEA	4×10^7	32	1	0	A + B + C
10	FEA	4×10^7	16	1	0	A + B + C
11	FEA	4×10^7	128	1	0	A + B + C
12	FEA	4×10^7	256	3	0	A + B + C
13	FEA	4×10^7	32	3	0	A + B + C
14	FEA	4×10^7	512	3	0	A + B + C
15	FEA	4×10^7	512	3	0	A + B + C
16	FL†	4×10^7	16	1	0	A + B + C
17	FL	4×10^7	128	1	0	A + B + C
18	FL	4×10^7	512	1	0	A + B + C
19	FL	4×10^7	64	3	0	A + B + C
20	FL	4×10^7	256	3	0	A + B + C
21	FL	4×10^7	512	3	0	A + B + C

Cats were approximately 6 months old at the start of the experiment and had no demonstrable specific antibody at that time.

* FEA, feline embryo fibroblasts grown as monolayers.

§ Simultaneous administration of 4×10^{10} *B. pertussis* and 1 ml Freund's complete adjuvant.

the immune system. Second, we considered it likely that the integrity of the glycoprotein complexes which are the effective immunogens might be well preserved by this presentation.

Feline embryonic fibroblast cells of the FEA strain were grown as monolayers (FE) and were infected with FeLV as previously described⁷; isolates containing various FeLV subgroups (A; A + B; and A + B + C) were used⁸. Cells were collected, washed three times in Alsever's solution and pelleted by low speed centrifugation. Minimal buffer was added to enable the cell pack to pass through an 18 gauge needle for subcutaneous injection.

Serum samples were taken before inoculation and afterwards at monthly intervals. Detailed haematological examinations were made to check for the possible development of anaemia, leukaemia or the thymic deficiency and immunosuppression syndrome, all of which are caused by FeLV infection. When the animals were killed they were examined for the presence of FeLV by two methods. Preparations of bone marrow and tracheal epithelium, the two most sensitive monitoring sites², were examined electron microscopically (EM). Bone marrow cells were also co-cultivated with FE cells growing as monolayers. The latter were then subcultured every 3 to 4 d for 21 d. The cells were divided; one aliquot was used to prepare sections for EM examination and the other was examined for the presence of FeLV group specific antigen by an indirect immunofluorescence test using goat anti-FeLV antiserum¹.

The results are shown in Table 1. When 2×10^9 cells were given, high antibody titres resulted and these persisted for at least 13 months. It will be seen from Fig. 1c that these cats did not reach their maximum antibody titre for 3 months; after they were killed, virus was found in the bone marrow. In contrast, cats which were inoculated with 4×10^7 cells (cats 8 to 15), produced good antibody response by 1 month after inoculation (Fig. 1a) and no virus was found in tissues taken at necropsy. At no time did any of these animals show a clinical or haematological abnormality

and no lesions were seen at necropsy or found on histological examination.

This experiment was repeated (Table 1, cats 16 to 21) using infected feline lymphoblasts grown in suspension culture; again a mean antibody titre of 128 was obtained. Virus was not detected at autopsy 1 or 3 months after inoculation and the cats remained healthy throughout. It is obvious from Fig. 1a and b that a rapid antibody response occurred in the first month to near peak titre. It is not known if these cats became infected during the first month or if the infection was suppressed by the rapidly rising antibody level. We are currently carrying out a larger experiment to allow weekly monitoring for infection during the first month. It would appear, however, that it is possible to obtain high titres using infected cells. In the small number of cases in which adjuvants were incorporated (Table 1) there was no apparent benefit and the peak antibody titre was not reached until the 4th month.

We have found that if cats which have naturally acquired specific antibody are inoculated with infected cells or purified virus, a secondary response results. The animal in Fig. 2a, which was typical of several, had a naturally occurring titre of 16. It was inoculated with 4×10^7 FeLV-infected FE cells and showed a rapid and high response. Virus could not be detected after autopsy. Another case from a different experiment is shown in Fig. 2b. This cat had a preinoculation titre of 8. It was given intravenously a purified FeLV preparation containing approximately 10^{10} virus particles when it was 4 months of age. There was viraemia between months 3 and 7, but during this period there was an antibody rise. The animal remained healthy until killed; there was no demonstrable virus in samples taken at autopsy. At the start of this experiment, none of the other nine animals involved had antibody. All became infected and three developed leukaemia during the limited time span of the experiment. The low antibody response of this group is shown in Fig. 2b.

Fig. 2 a, This young adult cat had 5 antibody units acquired by natural exposure to infection. It was inoculated with 4×10^7 FeLV-infected FEA cells subcutaneously. A high antibody titre was found at 1 month. No virus could be detected when the animal was killed after 2 months. b, A young adult cat had 4 naturally acquired antibody units. It was infected with a high dose of gradient purified virus which is normally 100% pathogenic. Viraemia was present after 3 months. Virus then disappeared and none was found at autopsy. At this time a high antibody level was present. c, Gives the mean antibody response of the other nine cats in this experiment. None had antibody titres before inoculation with virus and all became infected; three developed leukaemia before the experiment was terminated.

The following conclusions may be drawn from these results. If the cat had previous experience of FeLV and had responded immunologically even to a mild degree, a secondary response occurred and no persistent infection resulted. If the virus input dose was high, the animal became infected but subsequently suppressed the infection. Cats with no previous experience of infection seemed to have a cell dose-related response. The higher doses induced a good antibody level but this did not terminate the infection, even when observed over a long period. The persistence of infection may have been associated with the slower rate of antibody rise and its inability to prevent the establishment of infection of epithelial cells of many tissues¹. These cells may not be susceptible to the action of cytotoxic antibody. In the groups given lower doses the antibody rise took place in the first month and virus was not found in the animals at that time or later.

The mean antibody levels achieved in these experiments are considerably higher than those seen in cats with naturally acquired infections. The highest titre we have seen in a spontaneous feline leukaemia case was 32, and this was exceptional. Seventy-five per cent of cases had no demonstrable antibodies and the mean level of those which had was 8. In our surveys of normal cats, the highest titre seen in those which had antibodies was 64 and the mean was 4.

These results indicate the feasibility of vaccination against leukaemia by inducing either large primary responses or small primary and large secondary responses. As leukaemia and its associated diseases are not usually found in immature cats and as most animals seem to become infected horizontally by contact later in life^{1,2}, the time scale of the natural history of the disease is suitable for the application of immunisation. We have already obtained significant antibody levels with inactivated vaccines; these experiments will be reported later.

Two Distinct Types of Capping of Surface Receptors on Mouse Lymphoid Cells

IMMUNOGLOBULIN (Ig) molecules on the surfaces of metabolically active mouse lymphocytes are redistributed into "caps" when crosslinked with fluorescent, ferritin-conjugated or ¹²⁵I-labelled anti-Ig antibody at room temperature or 37°C¹⁻³. Caps of labelled Ig-anti-Ig complexes form over the Golgi region of the cell, and are rapidly ingested by endocytosis^{2,3}. Capping of receptors for the plant lectin concanavalin A

(con A) on mouse lymphoid cells is also accompanied by considerable endocytosis of label^{3,4}. On the other hand, little or no internalisation of label occurs after capping of H-2^{1,3} and Thy-1 (θ)¹ alloantigens on mouse lymphocytes and thymocytes, and anti-lymphocyte globulin receptors on rat spleen cells³.

To better define the relationship between cap formation and endocytosis, we examined capping of surface Ig, con A receptors, and H-2, Thy-1 and TL alloantigens on mouse thymus and spleen cells by immuno-electron microscopy and immunofluorescence. We report that caps form primarily in two distinct locations on the cell surface, either over or directly opposite the Golgi region. Location of capping seems to be determined more by cell type than by surface receptor, with caps generally forming over the Golgi region of spleen cells, and opposite the Golgi region of thymus cells. Caps over the Golgi region are extensively internalised by endocytosis, but there is little or no internalisation of caps forming opposite the Golgi region. Furthermore, cap formation over the Golgi region was partially inhibited by cytochalasin B, while capping opposite the Golgi was unaffected.

For these studies, mice of the C57Bl/6/TL+ congenic stock were used. Suspensions of thymus and spleen cells with greater than 90% viability (determined by trypan blue exclusion) were prepared in medium 199 supplemented with 5% (v/v) gamma globulin-free foetal bovine serum, and cells were incubated and washed in this medium. All incubations were for 30 min at 37°C, with cells maintained in suspension by periodic agitation. Cells were washed twice by centrifugation at 4°C after each incubation.

The following mouse alloantisera were used to label H-2, Thy-1 and TL alloantigens: (C57Bl/6/H-2^k × A)F₁ anti-C57Bl ascites leukaemia EL4 (anti-H-2^b), (A/Thy-1.1 × AKR/H-2^b)F₁ anti-A strain spontaneous leukaemia ASL1 (anti-Thy-1.2), and (A/TL- × C57Bl/6)F₁ anti-ASL1 (anti-TL.1,2,3).

Alloantigens on thymus cells were labelled for immuno-electron microscopy by incubating cells sequentially with the

Fig. 1 Section through the approximate centre of a spleen cell, with a cap of con A receptors, labelled with con A, hybrid anti-con A/anti-ferritin antibody, and ferritin, directly over the Golgi region (G). The cap of ferritin is marked by a bracket, and label internalised in vesicles is indicated by arrows. (×17,100.)

Table 1 Site of Cap Formation and Amount of Endocytosis of Cell Surface Receptors

Receptor	Cell	Over Golgi	No. of caps		Endocytosis of label
			Opposite Golgi	Intermediate	
Surface immunoglobulin	Spleen	28	0	2	++++
Con A receptors	Spleen	10	2	0	++++
H-2 alloantigen	Thymus	3	12	5	±
	Spleen	10	11	8	++
Thy-1 alloantigen	Thymus	1	9	2	±
	Spleen	12	2	0	+++
TL alloantigen	Thymus	2	18	5	—

appropriate alloantiserum (anti-H-2 and anti-Thy-1 were diluted 1:10, and anti-TL 1:100), then with the hybrid rabbit F(ab')₂ antibody, anti-mouse IgG/anti-ferritin⁴, and finally with ferritin. Hybrid antibody induces cap formation in the same manner, and nearly as effectively, as bivalent antibody⁵. Hybrid antibody directed against the Fc fragment of mouse IgG (anti-mouse Fc/anti-ferritin) was used on spleen cells, to discern applied alloantibody from naturally-occurring surface Ig⁶. Surface Ig was labelled with hybrid anti-mouse IgG/anti-ferritin and ferritin, and con A receptors with purified con A⁷ (100 µg ml⁻¹), hybrid anti-con A/anti-ferritin antibody, and ferritin. Hybrid antibodies and ferritin were used at a concentration of 100 µg ml⁻¹.

For immunofluorescence, alloantigens were labelled with alloantiserum and either 300 µg ml⁻¹ of fluorescent rabbit anti-mouse IgG (on thymus cells) or 250 µg ml⁻¹ of fluorescent rabbit anti-Fc fragment of mouse IgG (on spleen cells). Surface Ig was labelled with fluorescent rabbit anti-mouse IgG (130 µg ml⁻¹), and con A receptors with con A and fluorescent rabbit anti-con A (200 µg ml⁻¹). The purified IgG fraction of rabbit antiserum was coupled to fluorescein isothiocyanate by the method of Cebra and Goldstein⁸.

To determine the site of cap formation relative to the Golgi region of the cell, and to estimate the amount of internalisation of label, cell suspensions were first labelled for immuno-electron microscopy and then allowed to settle onto a carbon-coated glass surface before preparation for electron microscopy. We found previously⁹ that lymphoid cells usually settle onto a surface with the Golgi region oriented to one side. Serial sections were cut parallel to the plane of the monolayer, from which sections through the approximate centre of the cell, including the Golgi region, were selected for analysis. The approximate amount of endocytosis of label was estimated from the number of cytoplasmic vesicles containing ferritin. Results are presented in Table 1.

Surface Ig and con A receptors capped over the Golgi region on 93% and 83%, respectively, of spleen cells analysed, and the caps were extensively internalised (Fig. 1). In contrast, H-2, Thy-1 and TL alloantigens capped over the Golgi region on only 15%, 9% and 8% of thymus cells, respectively. Caps on these cells formed predominantly directly opposite the Golgi region, and very little endocytosis of label was observed (Fig. 2). Although Thy-1 alloantigen capped primarily opposite the Golgi region on thymus cells, 86% of caps of the same alloantigen on spleen cells formed over the Golgi region, and there was considerable endocytosis of label. These results suggest that the cell type, rather than the receptor, determines the cellular site of cap formation, and that the amount of endocytosis depends on the site of cap formation. Capping of H-2 alloantigen on spleen cells was not polarised, and endocytosis occurred to a moderate extent, primarily in cells with caps in the vicinity of the Golgi region. Capping of con A receptors on thymus cells occurs too infrequently for accurate determination of the predominant site of cap formation by immuno-electron microscopy.

We attempted to differentiate further these two types of cap by testing the effects of inhibitors of active cell movements on

cap formation. These results, obtained by immunofluorescence, are summarised in Table 2. Sodium azide, which may suppress cell movements by blocking intracellular ATP formation¹⁰, inhibited capping of all surface receptors to a similar extent. However, cytochalasin B, which prevents cell locomotion by disrupting cytoplasmic contractile microfilaments¹¹, strongly inhibited capping of surface Ig, con A receptors and Thy-1 alloantigen on spleen cells, but had only a slight inhibitory effect on capping of H-2 alloantigen on spleen cells, and virtually no effect on capping of the other surface receptors. Inhibition of cap formation was readily reversed by incubating treated cells in medium lacking cytochalasin B.

Since cytochalasin B was dissolved in dimethyl sulphoxide (DMSO) before use (100 µg ml⁻¹ in medium 199 containing 10% DMSO), DMSO at the same concentration used in conjunction with cytochalasin B was tested alone for its effects on capping. Results indicate that the differential effect of cytochalasin B on cap formation is not due to the DMSO vehicle. Furthermore, although cytochalasin B has been shown to suppress glucose uptake by cells¹², the observed inhibition

Fig. 2 Section through the approximate centre of a thymus cell, with a cap of TL alloantigen, labelled with anti-TL alloantiserum, hybrid anti-mouse IgG/anti-ferritin antibody, and ferritin, directly opposite the Golgi region (G). The cap of ferritin is marked by a bracket. No internalisation of label is evident. (×17,100.)

Table 2 Effect of Inhibitors of Active Cell Movements on Cap Formation

Receptor	Cell	% Inhibition of capping*				
		Sodium azide (10^{-1} M)	Cytochalasin B (5×10^{-4} M)	DMSO (10^{-1} M)	Vincristine (5×10^{-4} M)	Vinblastine (5×10^{-5} M)
Surface immunoglobulin	Spleen	75	57	7	3	4
Con A receptors	Spleen	86	81	3	0	2
H-2 alloantigen	Thymus	80	7	6	2	0
	Spleen	71	15	8	6	5

	Spleen	86	54	4	5	4
TL alloantigen	Thymus	86	6	6	1	0

* Cells were incubated with the appropriate inhibitor for 15 min at 37° C before immunofluorescence labelling in the continuous presence of the inhibitor. Inhibitors were used at the maximum concentrations at which 80% or more of the treated cells remained viable when labelling was completed. Each figure represents an average of three or more determinations.

of capping is apparently not due to impaired glucose uptake, since labelling of cells in medium lacking glucose had no effect on capping of surface receptors on either thymus or spleen cells.

Vincristine and vinblastine, two anti-mitotic alkaloids which precipitate microtubule proteins¹³, have no significant inhibitory effect on either type of cap formation (Table 2). Colchicine, colcemid and strychnine, drugs which have related effects on cellular microtubules¹⁴, also had no effect on either type of capping when used at a concentration (5×10^{-4} M) at which 80% or more of the treated cells remain viable.

The sensitivity of capping over the Golgi region of spleen cells to cytochalasin B indicates that this type of cap may form as a result of active cell movements mediated by a system of cytoplasmic contractile microfilaments. Capping opposite the Golgi region of thymus cells apparently does not result from the activity of contractile microfilaments or microtubules. Nevertheless, inhibition of this type of capping by sodium azide suggests that some sort of active cell movements is involved. Capping over the Golgi region and extensive endocytosis of capped label may require cell movements controlled by a system of contractile microfilaments, with capping opposite the Golgi region occurring in the absence, or during inactivity, of such a system. The lack of polarity, and relative insensitivity to cytochalasin B, of H-2 alloantigen capping on spleen cells may, however, indicate that there are additional factors involved in determining the cellular site of cap formation.

T cell factor which can replace T cells in vivo

THE mechanism whereby thymus-derived (T) and bone marrow or bursa-derived (B) lymphocytes cooperate in the induction of an antibody response is of great importance in immunology. It has been suggested that T cells concentrate antigen by their surface receptors to present a multideterminant antigen array directly to B cells^{1,2}; or that T cells secrete a special class of cooperating antibody (IgX) for this purpose, which could specifically present antigen at the surface of a third cell, the macrophage^{3,4}; or that the product of recognition of antigen by T cells has some non-specific mitogenic or stimulatory effect on B cells^{5,6}. Recent work with *in vitro* systems has indicated that various factors produced by T cells, either after contact with a specific antigen or following stimulation by allogeneic cells, can replace the requirement for T cells in antibody formation⁷⁻¹⁴.

Here, I describe the preparation of a T cell factor capable of totally replacing T cells *in vivo* in the induction of an antibody response to a highly thymus dependent synthetic polypeptide antigen, (T,G)-A--L. The factor is prepared *in vitro* by incubation of primed or 'educated' mouse T cells with antigen for 6-8 h; cells are then removed by centrifugation and the supernatant containing the factor is mixed with

* Direct anti-(T, G)-A--L PFC measured 12 d after transfer of supernatant with 10^7 bone marrow cells and $10 \mu\text{g}$ (T, G)-A--L into irradiated recipients.The direct anti-(T, G)-A--L plaque forming cell response in irradiated (850 r.) Balb/c mice 12 days after receiving transfer of syngeneic B cells mixed with (T, G)-A--L and supernatants produced *in vitro* by different combinations of normal or educated T cells and antigen. Results as geometric means of 15 mice \pm s.e.

normal bone marrow cells and antigen and transferred into lethally irradiated recipients. Under these conditions antibody-forming cells are produced in the spleens of the recipients in numbers identical with those produced by mixtures of T cells, B cells and antigen. Moreover, the T cell factor has been shown to be completely specific for the inducing antigen.

Experiments used Balb/c mice, bred at the Department of Pathology, Cambridge. The antigen was the multichain synthetic polypeptide poly-(Tyr, Glu)-poly-DL Ala--poly-Lys, abbreviated as (T,G)-A--L, and was the gift of Dr Edna Mozes.

T cells were 'educated' or primed to (T,G)-A--L by transfer of 10^8 Balb/c thymocytes into lethally irradiated (850 rad) syngeneic recipients, followed 1 d later by injection of $10 \mu\text{g}$ (T,G)-A--L in complete Freund's adjuvant. The spleens of these recipients, containing the educated T cells, were removed 7 d later, and contained approximately 5×10^6 viable lymphocytes per spleen by the criterion of trypan blue exclusion. Cell suspensions from the spleens were prepared in minimal Eagle's medium (Flow) with no further additions of protein or nutriment, with 10 spleen equivalents of cells per 5 ml of medium. (T,G)-A--L to a final concentration of $1 \mu\text{g}$ per ml was added and the cells incubated in small Petri dishes (Sterilin P 122, 50 mm \times 13 mm) at 37°C , under an atmosphere of 10% CO_2 . The type of Petri dish used is important, since dishes of different grade and manufacture (Falcon Tissue Culture Dishes) gave very unsatisfactory results.

Incubation was continued for 6–8 h, after which the cell suspensions were transferred to a centrifuge tube and the cells spun down. The cell-free supernatant was tested for its ability to cooperate with B cells by mixing with bone marrow

cells and antigen and transferring into lethally irradiated syngeneic recipients. Each recipient received supernatant equivalent to 1 spleen of educated T cells, 10^7 bone marrow cells, and $10 \mu\text{g}$ of (T,G)-A--L dissolved in saline, inoculated into a tail vein. Suitable controls were included as described below.

Twelve days later the spleens of these animals were removed and direct plaque-forming cells (PFC) to (T,G)-A--L determined. For the plaque assay, sheep red blood cells were coated with (T,G)-A--L by mixing equal volumes of packed sheep erythrocytes, chromic chloride (10 mg ml^{-1}), and (T,G)-A--L (2 mg ml^{-1}). After 5 min at room temperature the coated cells were spun down and washed three times. The results shown in the tables are geometric means \pm s.e. with 15 animals per group.

Table 1 shows that the supernatant produced by T cells educated to (T,G)-A--L was able to cooperate with B cells when transferred together into irradiated recipients. The level of the plaque forming response was very much higher than that given by B cells alone, and not significantly different from the response of B cells and 10^8 normal or 5×10^6 educated T cells. Thus, after a relatively short period of incubation with antigen *in vitro*, educated T cells released a factor or factors capable of replacing T cells in a cooperation-dependent antibody response *in vivo*. The conditions required for production of the factor *in vitro* are shown in Table 2. There was an absolute requirement both for educated T cells and the inducing antigen. Neither normal thymocytes, nor T cells primed against a non-cross-reacting antigen (sheep red blood cells) released any significant cooperating activity when incubated *in vitro* with (T,G)-A--L; and T cells educated specifically to (T,G)-A--L only released factor in the presence of (T,G)-A--L.

The specificity of action of the supernatant factor produced to (T,G)-A--L was investigated by transfer together with B cells and a non-cross-reacting thymus-dependent antigen, sheep red blood cells. Table 3 shows that the enhancing activity of the supernatant was specific for (T,G)-A--L and was completely without effect on the response to sheep red blood cells.

The possibility of contamination of educated T cells by B cells must be considered. No anti-(T,G)-A--L PFC were present in the educated T cell preparations, and no amount of conventional anti-(T,G)-A--L antibody tested could replace the requirement for T cells or T-cell factor *in vivo* (personal observation). To demonstrate conclusively that T cells were responsible for the production of the factor, educated T cells were treated with mouse anti- θ serum and complement before culture with antigen *in vitro*. (Anti- θ serum, raised in AKR mice to CBA thymocytes, was the gift of Dr A. Munro.) After treatment with anti- θ serum (or normal mouse serum as control) at a dilution of 1:2 for 30 min, the educated T cell preparation was washed and treated in the cold with guinea pig complement, previously

T cells educated to (T, G)-A--L were treated with anti- θ serum and complement, or normal mouse serum and complement, before culture with (T, G)-A--L *in vitro*. The factors produced by the surviving cells cultured with (T, G)-A--L *in vitro* were transferred together with B cells and (T, G)-A--L into irradiated Balb/c recipients. The results show the direct anti-(T, G)-A--L plaque forming cells 12 d after transfer. Results as geometric means of $15 \pm$ s.e.

absorbed with agarose and at a dilution of 1:10. Dead cells were subsequently removed by passage through a cotton wool column in low ionic strength buffer after the method of Von Boehmer and Shortman¹⁵. The effluent cells were restored to normal buffer conditions and cultured *in vitro* with antigen for 8 h. Table 4 shows that cells treated with anti- θ serum and complement were unable to produce factor to (T, G)-A--L *in vitro*, whereas controls treated with normal mouse serum and complement showed undiminished ability to produce the active factor.

The cooperating factor described can be compared with that described by Feldmann and coworkers^{4,7}, which is produced by activated T cells *in vitro*, is active in collaborating with B cells *in vitro*, and is also antigen-specific in its induction and action. Its *in vivo* properties have not been reported. On the other hand, there is a clear contrast with various non-specific enhancing factors produced by T cells in response to to allogeneic stimuli^{8-10,12,13} or other strong antigenic stimuli¹⁴.

It is possible that under physiological conditions *in vivo*, the joint action of two factors is required to initiate an antibody response in B cells. The first would be a T-cell product endowed with specificity—presumably through an antibody-like combining site—which could present the antigen in a multivalent fashion to B cells, for example by effectively polymerising antigen at the macrophage surface^{3,4}. The high strength of binding to B cells achieved thereby would be one prerequisite for effective antigen recognition by B cells and for B cell triggering. The other requirement would be a non-specific mitogenic stimulus provided by a second T-cell product, needed to send the B cell into proliferation. An excess of the latter product—as produced by allogeneic stimuli (the 'allogeneic effect')^{5,6,18}—could override the requirement for the former and for multivalent binding of antigen to B cells, by providing unusually high mitogenic stimulation. Thymus-independent antigens would be expected to possess multiple antigenic determinants of the same specificity, and in addition to have an independent mitogenic effect on B cells^{16,17}, thus circumventing T cells altogether.

Studies are in progress to identify the factor described here and in particular to determine whether it comprises more than one active component.

Demonstration of suppressor T cells in a population of 'educated' T cells

THE regulation of the immune response, in the sense of the limitation of its extent, can probably be achieved in two main ways. The first, and more extensively studied, is the feedback effect of the antibody end-product, brought about either by the removal of antigen, or by the blockage of antigen recognition by antigen-sensitive cells¹. A second possibility suggested more recently is that certain regulatory cells exist which can exert an actively suppressive influence on immune responses². Since they are believed to be among the thymus-derived or T cell population, they may be termed suppressor T cells. Evidence for their existence includes the enhancement of certain responses by anti-lymphocyte serum³⁻⁵, the suppressive influence of graft-versus-host reactions^{6,7}, and recent observations on antigenic competition^{8,9}, infectious tolerance¹⁰, and allotype suppression¹¹.

Results as geometric means of 15 mice \pm s.e.

Here I describe a method for demonstrating the presence of suppressor T cell activity in a population of primed or 'educated' T cells. Educated T cells, on culture with antigen *in vitro* for a period of 6–8 h, release a specific cooperating factor which can replace T cells *in vivo*²². The cells remaining in culture at the end of this time have lost the ability to collaborate with bone-marrow-derived (B) cells *in vivo*. Instead, they can suppress the antibody response *in vivo*, as demonstrated by mixing them with normal T cells, B cells and antigen, and transferring into irradiated recipients. Suppression of the immune response by these cells is antigen-dependent, but non-specific in effect. These observations suggest the possible existence of two functional lines of T cells, one cooperative and the other suppressive, and indicates a convenient method for their separation.

The preparation, in Balb/c mice, of T cells educated to the synthetic polypeptide antigen (T,G)-A--L, and the subsequent culture of these cells with antigen *in vitro* has been described in the preceding paper¹². After 6–8 h culture, the cells were spun down and the supernatant removed. The cells were resuspended in cold Eagle's medium, washed twice, and finally resuspended to a concentration of about 5×10^6 viable lymphocytes ml⁻¹. Over the period of *in vitro* culture, a decrease in viability of 15–20% occurred as judged by trypan blue exclusion. The cells were tested for their ability to interact with B cells by transfer together with 10^7 bone marrow cells and (T,G)-A--L (10 μ g in saline per mouse) into irradiated (850 rad) syngeneic recipients. In some experiments, described below, 10^8 normal T cells (thymocytes) were also present in the mixture transferred. Twelve days after transfer, the direct anti-(T,G)-A--L plaque-forming cell (PFC) response in the spleens of these animals was measured as previously described¹². The results in the tables are geometric means of 15 mice \pm s.e.

T cells educated to (T,G)-A--L were able to cooperate with B cells *in vivo* (Table 1), provided they had not been previously cultured with antigen *in vitro*. After incubation with (T,G)-A--L *in vitro* for 6–8 h, the educated T cells could not collaborate with B cells *in vivo* in the response to (T,G)-A--L. Moreover, these cells caused the normal background response observed when B cells and (T,G)-A--L are transferred into irradiated hosts to drop to zero; this was the first suggestion that they were endowed with suppressive properties. This dramatic change in the *in vivo* activity of the educated T cell population did not occur if antigen was omitted from the *in vitro* culture system. Furthermore, the change was antigen-specific, since the cells continued to cooperate normally in the response to non-cross-reacting erythrocyte antigens (personal observation).

To test whether the educated T cells had indeed become actively suppressive after incubation with antigen *in vitro*, they were transferred together with B cells, 10^8 normal T

cells and (T,G)-A--L into irradiated hosts. The usually excellent PFC response produced *in vivo* by B cells and normal T cells was reduced by over 90% by the presence of 5×10^6 educated T cells previously cultured *in vitro* with antigen (Table 2).

The specificity of action of these (T,G)-A--L-induced suppressor T cells was examined by transferring them with normal T and B cells and a non-cross-reacting antigen, sheep red blood cells (SRBC), into irradiated hosts. In one group, (T,G)-A--L was also added. The anti-SRBC response was very significantly reduced by the presence of these cells (Table 3), provided the original educating antigen, (T,G)-A--L was also present. If (T,G)-A--L was omitted, however, then the suppressor T cells had no effect on the response to SRBC. Thus the suppressive effect of these cells was apparently non-specific, but the presence of the specific inducing antigen was necessary to elicit it.

It seems that the following events occur when educated T cells are cultured *in vitro* with antigen for 6–8 h. (i) A specific cooperative factor is released which collaborates with B cells *in vivo* in the induction of an antibody response to the educating antigen, as described in the preceding report¹². (ii) The cells lose the normal ability of educated T cells to collaborate with B cells *in vivo* in the response to the educating antigen. (iii) The cells display a potent suppressive influence on B cells and on mixtures of normal T and B cells *in vivo*. In contrast to the specific cooperative activity of educated T cells or the T-cell factor, the suppressive activity is non-specific in its effects, although the original educating antigen must be present for non-specific suppression to occur.

These results suggest the conclusion that a primed T-cell population contains two functionally distinct groups of cells, one of which is specifically cooperative, while the other is non-specifically suppressive. Brief *in vitro* culture stimulates the cooperative T cell population to release its cooperative factors, but also renders it apparently exhausted at the end of 8 h, although this exhaustion might be only temporary. The suppressive T cell population, on the other hand, is not exhausted by this *in vitro* incubation, and its activity is therefore seen to the full when the cells are transferred with B cells *in vivo*. It seems likely that the suppressor T cells release non-specific suppressive substances shortly after stimulation by antigen *in vivo*, as judged by the efficiency with which the response given by normal T and B cells to SRBC was suppressed by (T,G)-A--L-induced suppressor T cells and (T,G)-A--L. It is also probable that the suppressor T cells constitute an important physiological control mechanism *in vivo*, here demonstrated in the antibody response, but most

likely applying to cell mediated immunity also¹³. Other suppressive phenomena, including some forms of antigenic competition^{8,9}, infectious tolerance¹⁰ and the graft-versus-host reaction^{6,7}, may also be mediated by the same T cell subpopulation. The system described here provides a method for the functional separation of the cooperative and suppressive T cell lines, and should open the way to further clarification of their properties.

Cyclic GMP Response *in vivo* to Cholinergic Stimulation of Gastric Mucosa

INTEREST in cyclic guanosine 3',5'-monophosphate (cGMP) has been stimulated by the demonstration that its sister nucleotide, cyclic adenosine 3',5'-monophosphate (cAMP), is an intracellular mediator or 'second messenger' for many hormones, including noradrenaline, the neurohormone of the sympathetic nervous system¹. Reports concerning the possible implication of cAMP in gastric secretion in mammals are conflicting. The infusion of histamine increases cAMP in canine gastric juice² but does not stimulate adenylate cyclase activity of canine gastric mucosa³. A review of the subject has led to no consensus of opinion⁴.

An association of cholinergic stimuli with increased tissue cGMP has been described in several organs. Addition of acetylcholine (ACh) *in vitro* increased cGMP in rat heart and liver, rabbit brain, dog thyroid and guinea pig ileum⁵⁻⁸. Mouse brain showed an increase of cGMP with infusion of a cholinergic agonist but not after pretreatment with atropine⁹. Isolated strips of rat gastric fundus contracted when exposed to cGMP¹⁰.

To investigate the possibility that cGMP might be a mediator for cholinergic nervous stimuli in the stomach, an *in vivo* preparation making possible the direct stimulation of the vagus nerves was devised. Acid secretion was demonstrated by measurement of the pH of the gastric mucosal surface. Strips of gastric mucosa (dissected free of the underlying muscularis) were removed from (barbiturate)-anaesthetised adult mongrel dogs and instantly frozen in liquid nitrogen immediately before and after various experimental manipulations. The separation from the blood supply before completion of freezing never exceeded 5 s. The mucosal samples (1 to 2 g) were extracted with trichloroacetic acid and fractionated on a formate column. Cyclic GMP was assayed by radioimmunoassay^{11,12}. The

specificity of the assay was verified by demonstrating the absence of cross reactivity with cAMP and the major mono-, di-, and tri-phosphate nucleotides. Reproducibility was within 5%. Sensitivity was less than 2 pmol cGMP per g tissue. Known amounts of cGMP added to one of two identical samples were quantitatively recovered. ³H-cGMP was used as a recovery standard for the extraction process. All assays were run in triplicate.

Sham operations produced no change in mucosal cGMP content. Results of the various procedures are presented in Table 1. Electrical stimulation (30 pulses (10 ms, 22 V) s⁻¹ for 1 min) of the distal thoracic vagus nerves cut just above the diaphragm more than doubled mucosal cGMP in the fundus of the stomach but did not change antral mucosal cGMP. Pretreatment with intravenous atropine (0.2 mg kg⁻¹), a cholinergic antagonist, prevented the increase in fundic mucosal cGMP.

Table 1 Cyclic GMP Content of Canine Gastric Mucosa

	Fundus			Antrum		
	(pmol g ⁻¹)	N	P	(pmol g ⁻¹)	N	P
Baseline	28±2			49±4		
Vagal stimulation *	66±9	8	<0.001	45±5	5	<0.2

Baseline	30±2					
Pentagastrin infusion *	29±2	4	>0.5			
Baseline				72±6		
Vagal stimulation, fundus out				69±5	4	>0.5

* Acid secretion (reduced gastric mucosal pH).

Infusion of ACh iodide (0.05 mg in 1 min) into the coeliac artery produced a two-fold increase in fundic mucosal cGMP and no change in the antrum, duplicating the results of vagal stimulation. Cannulation of the coeliac artery for infusion was preceded by dissection of the sympathetic-rich coeliac plexus, which may account for an increase in baseline mucosal cGMP in these experiments. Vagal stimulation achieved by hypoglycaemia after intravenous injection (0.6 units kg⁻¹ in a bolus) of crystalline zinc insulin (blood sugar below 50 mg per 100 ml in all dogs) caused a nearly two-fold increase in fundic cGMP with no change in the antrum. Vagus section eliminated the fundic cGMP response to insulin.

Because changes in fundic mucosal cGMP could result from release of the hormone gastrin from the antrum in response to vagal stimulation, the effect of pentagastrin in concentration sufficient to produce acid secretion (1 µg kg⁻¹ over 6 min, infused intravenously) was tested. There was no effect on the cGMP content of the fundic mucosa. Thus, the increase in fundic cGMP with vagal stimulation does not appear to be mediated by gastrin or by the presence of acid in the stomach but is more likely a direct response to cholinergic stimulation.

It seemed possible that the gastric antrum might not be responding to vagal stimulation with a change in cGMP because of the suppressive effects of fundic acid on gastrin-producing cells in the antrum. Therefore, the fundus was resected in four dogs with vagal innervation of the antrum preserved intact, as shown by antral motility when the vagi were stimulated. After removal of this acid-secreting area, vagal stimulation still failed to alter antral mucosal cGMP. The high baseline cGMP in antral mucosa following fundectomy is unexplained.

These data demonstrate an association between several types of cholinergic stimulation of the stomach *in vivo* and an increase in canine fundic mucosal cGMP and suggest that cGMP may serve as a 'second messenger' for ACh, the 'first messenger' of cholinergic stimuli. Cyclic GMP may not perform this function in the gastric antral mucosa, but it is possible that antral mucosal cholinergic receptors are too few in number to raise cGMP to a level within the sensitivity of this assay. The results with gastric fundic mucosa add to the growing body of evidence linking cholinergic stimulation with increases in tissue cGMP.

Colchicine and Vinblastine Inhibit Fibroblast Aggregation

THE alkaloids colchicine and vinblastine interfere with the assembly of microtubules, yet they also affect several properties of the surface membrane of animal cells. They disorganise an apparent topographical separation between surface areas involved in membrane transport and in phagocytosis in rabbit polymorphonuclear leukocytes¹, inhibit the agglutination of these cells by concanavalin A (ref. 2) and inhibit the concanavalin A-dependent adherence of red blood cells to transformed 3T3 fibroblasts³.

We have now found that these alkaloids also inhibit the spontaneous aggregation of hamster fibroblasts (BHK 21, clone 13 (ref. 4)) which occurs when these cells are shaken in suspension, after dispersal from monolayers by exposure to trypsin in the presence of EDTA (ref. 5). We used experimental conditions and an assay involving the Coulter counter, with which we have previously shown that aggregation is suppressed at low temperature, reversed by low concentrations of proteolytic enzymes⁵, stimulated by neuraminidase⁶ and much reduced in a number of polyoma-transferred derivatives of BHK21 cells⁷.

The inhibition by the alkaloids (Figs 1 and 2) is less complete than can be obtained by treating the cells with high levels

Fig. 1 Inhibition of aggregation of BHK21 cells in suspension by 10^{-4} M colchicine ○ and 10^{-6} M vinblastine □, determined by Coulter counting. These suspensions and control minus alkaloids ● were all aggregated in Hanks' solution buffered with 0.01 M Hepes, pH 7.4. Cells were suspended at an initial density $N_0 = 1.0 \times 10^6$ cells ml^{-1} . Each curve was obtained from 4 ml of suspension incubated in a reciprocating shaker at 37°C in a 10 ml stoppered conical flask. 0.1 ml aliquots were diluted $\times 200$ for counting. The counter measures the total concentration N_t of cells plus cell-clusters.

of trypsin (J. G. E., J. A. Campbell, R. T. R., and M. Vicker, in preparation), and the inhibited cells aggregate more than do polyoma-transformed cells⁷. Vinblastine is effective at much lower concentrations than colchicine, colcemide is intermediate (Fig. 3). Our own unpublished observations show that these concentrations are similar to those required to alter the shape of BHK cells in culture from fibroblast-like to epithelial-like⁸. Lumicolchicine⁹ shows slight inhibition, but only at concentrations 100 times higher than the colchicine from which it was prepared by UV irradiation. The onset of inhibition is fast, occurring within the few minutes resolvable by the assay, and some disaggregation is commonly observed when vinblastine, for example, is added to a partly aggregated cell suspension (Fig. 4). In contrast to these effects on spontaneous aggregation, the agglutination of trypsinised BHK21 cells by concanavalin A seems to be wholly insensitive to the same inhibitors. This is true both for C13 cells (in which case lectin-induced and spontaneous aggregation are superimposed in the assay) and for trypsinised polyoma-transformed BHK21 cells (Fig. 5).

Vinblastine has a very different structure from colchicine, and inhibits aggregation at much lower concentrations. Lumicolchicine, which shares at least some of the non-microtubule effects of colchicine¹⁰, is essentially inactive. It therefore seems more likely that the effects we have observed result from interference with the assembly of microtubules than from some secondary, non-specific effect of the alkaloids on the cell surface. (A remaining problem is that our unpublished observations show that the effect of vinblastine is at least partially reversible, whereas effects of vinblastine on microtubules in some systems are not¹¹.) Microtubules are probably present in trypsinised BHK cells, although Goldman and Follett¹² found them rather sparse and randomly scattered throughout the cytoplasm. It is an intriguing problem how the integrity of microtubules could modify the probability that suspended cells will adhere to one another, and we consider here three possible mechanisms.

Fig. 2 Inhibition of aggregation by, *a*, 2×10^{-6} M vinblastine and, *b*, 10^{-5} M colchicine, measured by haemocytometry. The ordinate is the fraction of cells found after 45 min incubation in clusters containing the number of cells per cluster shown on the abscissa. Solid figures in the presence of inhibitor, open in absence. About 1,000 cells were counted for each distribution.

First, microtubules may influence the state of convolution of the surface. For example, trypsinised BHK cells are known to possess microvilli¹³ and a relation between fine projections from cell surfaces and cell adhesiveness has often been suggested^{14,15}. The microvilli of BHK cells seem, however, to contain microfilaments rather than microtubules, and are presumably not analogous to the filopodia of mesenchyme cells in the sea-urchin embryo¹⁶, or the axopodia of heliozoans¹⁷. The second mechanism depends on the assumption that the self-adhesiveness of trypsinised BHK cells requires some appropriate arrangement in the surface membrane of 'contact sites' such as those described in *Dictyostelium*¹⁸. We have no evidence for this, beyond a study of the kinetics of aggregation which previously suggested that trypsinised BHK cells behave as though they are adhesive only in patches¹⁹. Berlin has suggested that microtubules can stabilise arrangements of antigenic determinants and other functional elements which would otherwise be capable of rapid lateral diffusion in the membrane¹. This could be achieved by a direct linkage between microtubules and surface elements.

The third mechanism, which we favour at present, is suggested to us by the observations of Vasiliev *et al.* who found that colchicine and vinblastine caused the ruffling activity of fibroblasts locomoting in culture to spread from a restricted area to all parts of the edge of the cells²⁰. Such ruffling has been equated with the insertion, movement and recycling of surface membrane, perhaps by vesicles transported within the cell^{21,22}. Microtubules could be involved in the transport of such surface and perhaps focus its insertion to a restricted part of the cell surface. We propose that cell surface may be

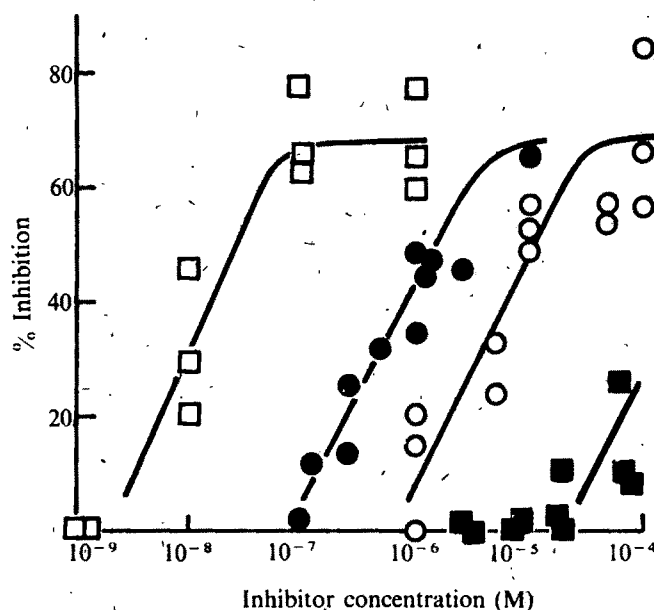

Fig. 3 Concentration dependence of the inhibition of aggregation by vinblastine \square , colcemide \bullet , colchicine \circ , and lumicolchicine \blacksquare . The ordinate is $\frac{N(\text{inhibited}) - N(\text{control})}{N_0 - N(\text{control})} \times 100$, determined after 45 min by Coulter counting as Fig. 1.

adhesive only immediately after undergoing such organised transport, so that aggregation would depend on continued operation of such a cycle. Such a mechanism could account for the sensitivity of aggregation to combined inhibition of glycolysis and respiration which we shall report elsewhere. It is tempting to speculate that a similar surface extrusion phenomenon could be involved in the ADP-dependent aggregation of platelets, which is also sensitive to metabolic inhibitors²³ and to colchicine and vinblastine²⁴.

Whatever the mechanism, if it proves to be true that microtubules can control the distribution of adhesive components in

Fig. 4 Kinetics of inhibition of aggregation by 4×10^{-8} M vinblastine, determined by Coulter counting. Vinblastine was added before shaking \square or at 15 min \blacksquare . No addition \bullet .

cell surfaces, this may be of considerable importance in the organisation of tissues, since it could provide a mechanism whereby cells relate their internal spatial organisation to their orientation with respect to neighbouring cells.

Explanation of Degree of Correlation of Sibling Generation Times in Animal Cells

SEVERAL methods are available for producing synchronous cultures of mammalian cells^{1,2}, but it is technically impossible to produce a culture which maintains a high degree of synchrony for more than one or two rounds of division because of the highly variable length of the period between successive mitoses from cell to cell. Variability of generation time is also observed in sibling cells formed by the division of a common parent. If cells are able to divide accurately siblings would be expected to be genetically and biochemically identical, and should therefore also have identical generation times but in fact while there is a clear correlation³⁻⁶ it is always imperfect.

In the past this heterogeneity has been implicitly explained in terms of the nature of the sequence of events which a cell must coordinate in order to divide successfully. Because it was considered to be so highly complex, it seemed reasonable to suppose that small differences at each step could accumulate and eventually lead to the great variability in the total intermitotic time observed, even in the case of siblings.

A model of the cell cycle has recently been proposed, however, which positively predicts a high degree of heterogeneity of generation times, but which, in contrast to more conventional models, places much the greatest part of the

Fig. 1 Semilogarithmic plot of % cells (α) undivided at time t , against t for BHK21/C13 cells. $P = (10 - 4.3)/10 = 0.57 \text{ h}^{-1}$.

Fig. 2 Correlation between the generation times of siblings for BHK21/C13 cells.

variation at a single point in the cell cycles. According to this theory, proposed in one form by Burns and Tannock⁷, and later by Smith and Martin⁸, there is a sequence of orderly and obligatory events which must be carried out for a successful division. A cell may be either performing this sequence of events, and therefore committed to division (when it is said to be in B phase), or it may be in the alternative condition which Smith and Martin termed the A state.

The A state is regarded as a 'limbo' in which a cell may remain indefinitely without ill effects. A cell in the A state is in no sense committed to division, but is in an unstable state in so far as it may so commit itself at any time, and its probability of doing so is greater the better its physiological condition. A cell in the A state is analogous to a radioactive nucleus in that both may 'decay', the cell into the division sequence of B phase, the radioactive nucleus into its products. Whereas a whole population of cells in the A state will decay at a rate governed by physiological conditions, and a population of radioactive nuclei will decay at a rate governed by the isotopic half-life; it is impossible to state that a specific cell in the A state, or a specific radioactive nucleus is about to decay. The cell's past history (that is, how long it has been in the A state) like that of the radioactive nucleus (how long it has been in existence) does not affect its probability of decaying in the immediate future. Consequently a population of cells in the A state, like a population of radioactive nuclei, will decay with first order kinetics while the time an induced cell spends in the A state is completely unpredictable and therefore by the definition of the word, completely random. It is this random element introduced by the existence of the A state which is said to produce the heterogeneity of intermitotic times in cell populations.

The model makes a number of quantitative predictions which were in good agreement with published observations⁸. The object of this work was to see if it could also provide an adequate explanation of the extent of the correlation of sibling generation times.

BHK21 C13 cells were grown on 30 mm plastic Petri dishes (Nunc, Roskilde) in Dulbecco's modification of Eagles medium supplemented with 10% calf serum. Cells were seeded as sparse cultures the day before filming began, and

gassed with 10% CO₂ in air during incubation at 37° C. Exposures were made at 60 s intervals for 24 h (about two generation times under the conditions used) and the individual intermitotic times measured by frame-by-frame analysis. A cell was said to have entered mitosis when it had completely rounded up before division.

The model predicts a specific type of distribution of intermitotic times. No cell will be able to divide in a time shorter than the length of the necessary sequence of events which makes up B phase (T_b). The remainder of the intermitotic time is entirely attributable to the time spent in the A state, and will therefore have a logarithmic distribution, so that a plot of the fraction of cells (α) having an intermitotic time greater than t against t will show that α remains constant at 100% for a period (which will be equal to T_b) and then decays exponentially just as a population of cells in the A state decays exponentially (because elements of the intermitotic time greater than T_b are spent in the A state). A total of eighty-eight intermitotic times was measured from the BHK cells and is plotted in this form in Fig. 1. The data deviate from the ideal, but for the purpose of discussion this will be assumed to be due to variation in the duration of B phase. On this basis T_b was estimated to be 9.5 ± 0.6 h and the transition probability (defined as the fraction of cells leaving the A state h^{-1}) to be $0.57 h^{-1}$.

The eighty-eight intermitotic times measured included a total of thirty-seven sibling pairs, whose intermitotic times were well correlated ($r=0.85$, $P \ll 0.001$). There was, however, as expected, noticeable scatter from the perfect correlation line (Fig. 2).

The model proposes a two-part cycle, one being the division sequence, and it will be assumed in what follows that this sequence is of identical duration in siblings, that is, that a cell is able to divide its genetic and biochemical capital with total accuracy between its progeny. The other part of the cycle, however, is of essentially random length, and totally independent of genetic or biochemical endowment for an individual cell, and so unrelated in siblings. On these assumptions, cells of cultures which spend a long period in

Fig. 3 Semilogarithmic plot of the number of sibling cell pairs (β) with differences in generation time greater than t against t for BHK21. C13 cells, compared with expected line calculated for $P=0.57 h^{-1}$, from Fig. 1. $\beta_t = \beta_0 P^t$, where $\beta_t = \beta$ at time t , P = transition probability.

the A state on average will have, on average, a larger random element in their cycle than cells of cultures which do not, and will therefore also have a greater scatter from the perfect correlation line than rapidly growing cells.

In fact it is possible to make a quantitative prediction concerning the distribution of the differences of intermitotic times of siblings on the grounds that as they represent the differences between times spent in the A state, they will have the same distribution as times spent in the A state. Expressed more rigorously, a transition probability of 0.57 h^{-1} (as here) means that a given cell in the A state has a probability of $(1.00-0.57)$ or 0.43 of not leaving the A state in the next hour. If two cells in the A state are considered at the time when the first one leaves, the second will have a probability

Fig. 4 Semilogarithmic plot of α and β against t for *Euglena gracilis* (data of Cook and Cook³). $P=0.44$.

of 0.43 of remaining in the A state for at least one more hour. Therefore if differences of the intermitotic times of siblings are considered (which have been assumed for the purposes of this treatment to be totally due to differences in the time spent in the A state) a fraction equal to 0.43 of the total will be greater than 1 h . Similar considerations may be applied to different time intervals, and it is consequently possible to deduce a theoretically expected line for the number of sibling pairs (β) whose intermitotic times differ by more than t , against t . Such a line is shown in Fig. 3 for the BHK cells with the actual differences observed. The fit is reasonably good, considering the small numbers involved. Figure 4 shows the plots of α and β for *Euglena gracilis* (data of Cook and Cook³) which involved a far larger number of cells. The agreement between the theoretical and actual distributions is good.

Most current ideas on the cell cycle make no quantitative predictions about the distribution of differences between siblings to be expected, and still less about the relationship between sibling differences and the overall variability of the population. Indeed, there is no *a priori* reason why such a relationship should exist.

In contrast the recently proposed model of the cell cycle^{7,8} does imply such a relationship, in that it should be possible to predict the distribution of the differences between sibling generation times from the distribution of generation times

directly. The data presented here are consistent with the distribution predicted in this way.

Autosomal recessive mutation in sugar response of *Drosophila*

THE molecular basis of sugar reception in vertebrates and insects still remains undefined. The fact that stimulation with a solution of a pair of sugars exhibits either synergism or an inhibitory effect^{1,2} suggests that multiple receptor sites are involved. Interactions of certain proteins with given sugars are known both in mammals^{3,4} and in insects^{5,6}, but their relation to sugar reception is not clear. Genetic alteration, which has been successful in studies of chemotaxis in a bacterium⁷ and olfaction in an insect^{8,9}, may throw a new light on such a complex system. For genetic dissection of sugar reception, *Drosophila* offers certain advantages. Methods for measurements of its sugar responses are readily available¹⁰, and procedures to isolate its mutants are well established^{9,11}. We shall describe here the first mutant of sugar response in *Drosophila*.

An isogenic line (AA75-3) of *Drosophila melanogaster*¹⁰ was maintained on the usual sucrose-corn-yeast extract medium. Males treated with the mutagen, ethylmethane-sulphonate (EMS)⁹, were mated singly for 4 d with untreated virgin females of the marker strain T5 having genotype *Cy/Pm*; *Ubx/Sb* (*Cy*, *Curly* wings with inversions; *Pm*, *Plum* eye colour; *Ubx*, *Ultrabithorax* halteres with inversions; *Sb*, *Stubble* bristles) with an attached X chromosome, and transferred to be mated with new females of the marker strain T5 for another 4 d. Each F_1 progeny male of *Cy/+*; *Ubx/+* was then backcrossed to three virgins of the marker strain T5. Thus homozygotes, the autosomes of which came from one side of the chromosomal pair of each treated male, were isolated in descendants. From about 1,200 F_1 males, only 100 isogenic lines were obtained (about 300 lines possessing autosomal recessive lethal genes have been maintained with *Cy* or *Ubx*, and others were lost due to the lethal effects of the mutagen).

To detect suspect lines revealing abnormal behaviour, we examined changes in sugar responses of about 100 isogenic lines of flies aged 0-3 d with the preference-aversion test according to Isono *et al.*¹⁰, using a balanced system with the following four stimulants placed in four small glass rings in a Petri dish: distilled water, $5 \times 10^{-2} \text{ M}$ D-fructose, $7 \times 10^{-2} \text{ M}$ D-glucose and $2 \times 10^{-2} \text{ M}$ sucrose each in a 2% agar solution. Concentrations of sugars were determined so as to attract the parent flies (parent strain AA75-3) at a ratio of about 1:1:1:0.2 for fructose, glucose, sucrose and water, respectively. The unbalance of the ratio resulting from changes in responses of flies to any of these three

TABLE 1 Responses of mutant, parent, F₁ and F₂ hybrid flies to sugars

Sugars	Concentration (M)	Number of impulses/0.2 sq*			
		Parent	Mutant	F ₁ hybrid†	F ₂ hybrid‡
Sucrose	10 ⁻²	15.7	13.2§	15.5	14.7
	10 ⁻¹	24.6	26.0	25.6	25.9
	10 ⁻²	19.9	17.8§	19.7	19.7
Maltose	10 ⁻¹	25.2	24.5	25.0	25.4
	10 ⁻²	6.7	6.1	6.6	6.7
	10 ⁻¹	15.7	15.0	14.9	15.9
D-Fructose	10 ⁻²	10.6	3.4¶	9.6	6.4
	10 ⁻¹	19.6	14.5¶	19.4	17.5

* Average number of impulses originating in sugar receptors of labellar single chemosensory hairs of *Drosophila* flies aged 0–2 d during 0.2–0.4 s after initiation of stimulations by the 'tip recording method'. Number of stimulations was about 2,000 with 267 hairs of 89 flies (45♂, 44♀).

† Coming from two reciprocal classes of single crossings of mutant with parent.

‡ Coming from two reciprocal classes of single crossings of F₁ hybrid with mutant.

§ ¶ Significantly different from parent (§, $P < 0.05$; ¶, $P < 0.01$).

|| Significantly different both from parent and mutant ($P < 0.05$).

sugars could be seen at once. Of about 100 lines examined, one line of flies (126B04) showed a marked decrease in response to glucose, giving an average ratio of about 1.2:0.3:1.1:0.2 for fructose, glucose, sucrose and water, respectively.

Such behavioural changes seem to be a consequence of functional modifications in the chemosensory hairs. To define the regions where modifications were involved, nerve responses of labellar chemosensory hairs of the mutant flies (line 126B04) were compared with those of the parent by the 'tip recording method' used in studies of contact chemoreception in dipterous insects^{10,12}. The nerve responses of flies aged 0–2 d were recorded from the tips of three particular type-L labellar single hairs with a glass capillary filled with sugar dissolved in 10⁻⁴ M NaCl solution, which served as a stimulator and recording electrode, and an indifferent electrode inserted into the back of the head¹⁰. Experiments were done at 20° C in a relative humidity range from 60 to 70.

Column 3 and 4 of Table 1 show the average number of impulses originating in the sugar receptors of single hairs of both mutant and parent flies during 0.2–0.4 s after the initiation of the stimulations by 10⁻¹ and 10⁻² M sucrose, maltose, glucose and fructose. The responses of the mutant flies to glucose are drastically different from those of the parent, the average difference being about 5.1 and 7.2 impulses for 10⁻¹ and 10⁻² M glucose, respectively; whereas, with both 10⁻¹ and 10⁻² M fructose, the mutant flies reveal phenotypes similar to those of the parent. The changes of responses in the mutant flies to both sucrose and maltose seem to be dependent on the mutation present; although the mutant flies responded normally to 10⁻¹ M of those sugars, they revealed reductions of about 2.5 and 2.1 impulses for 10⁻² M of sucrose and maltose, respectively. In addition to these four sugars, the labellar hairs of the mutant flies were completely insensitive to 1 M D-galactose, D-mannose and D-xylose, and 3 × 10⁻¹ M lactose as expected from the results with the parent flies¹⁰. Male flies revealed phenotypes similar to those of females of the same strain in response to stimulations by sucrose, maltose, glucose and fructose (for example, 14.6 and 14.4 impulses, to 10⁻¹ glucose, and 3.7 and 3.1 impulses to 10⁻² M for males and females of the mutant flies, respectively). This indicates that the mutation present can be independent of the sex chromosomes, and probably is in the autosomes.

Column 5 of Table 1 shows the average magnitudes of nerve responses of the 20 F₁ hybrid flies, which came from two reciprocal classes of several single crossings of the mutant flies with the parent. It is evident from this table that the F₁ hybrid flies reveal phenotypes similar to those of the parent in response to the four sugars. No significant

difference in response was recognised between sexes. From the above results, we conclude that the mutation is autosomal recessive.

Column 6 of Table 1 shows the average values of impulses of the 40 F₂ hybrid flies, coming from two reciprocal classes of several single crossings of the F₁ hybrid flies with the mutant. The F₂ hybrid flies revealed phenotypes similar to those of the parent in response to sucrose, maltose and fructose; whereas to both 10⁻¹ and 10⁻² M glucose, the F₂ flies gave responses intermediate to those of the parent and mutant strain. Male F₂ hybrids showed similar magnitudes of response to their females. An attempt to define segregations of the F₂ hybrids between phenotypes of both strains on the basis of their responses to stimulation by 10⁻¹ and 10⁻² M glucose has been unsuccessful because of marked variations within each group of the parent and mutant flies, which deterred us from drawing an arbitrary line within the F₂ hybrid flies.

Although the mutation could not be defined other than that it is an autosomal recessive, the fact that the mutant flies revealed simultaneous modifications in response to glucose, sucrose and maltose, though they showed normal responses to fructose, implies that at least two different receptor sites are involved in labellar chemosensory hairs of *Drosophila*. If further genetical analysis shows that the mutation is governed by a single gene, comparisons of the mutant flies with the parent will lead to isolation and identification of receptor sites in the labellar chemosensory hairs.

Blood Glucose and Nutritive Antibiotic Activity in Ruminants

NUMEROUS monogastric species respond to the continuous ingestion of small amounts of certain antibiotics by increased growth and improved feed utilisation. The mode of action of this so-called "nutritive effect" is not well understood, although various alterations in the intestinal flora have been observed as well as changes in the intestinal mucosa, indicating improved nutrient absorption.

Ruminants also exhibit growth responses to some antibiotics, but here the mode of action is even less clear. Changes in the rumen metabolites and flora are likely to occur, and hypotheses trying to explain the antibiotic growth response in ruminants are largely based on altered rumen fermentation¹. No consistent changes in rumen or host metabolism have so far been demonstrated, however, which could be related to growth responses.

Leskova and Zucker² have recently reported that the growth response of early weaned calves to the new phospholipid-antibiotic Diumycin (SFI 80.586) was accompanied by elevated blood glucose levels. This antibiotic has a predominantly Gram-positive spectrum and is not active against protozoa. It is not absorbed and therefore its primary action should be confined entirely to the lumen of the intestinal tract. Antibiotic levels of 5 and 10 p.p.m. in the feed were employed, the lower level corresponding to approximately 0.1 mg, or less, per kg of body weight. The calves were fed a complete pelleted feed (maize 40%, oats 15%, alfalfa meal 17%, soya bean meal 25%, minerals and vitamins 3%) with hay.

The results of two experiments are shown in Figs 1 and 2. Similar increases of weight gains and blood glucose levels have been measured in two additional experiments. There were no changes in serum lactate levels. Serum urea concentration decreased significantly in calves receiving the antibiotic, indicating increased protein synthesis³. Diumycin improved feed utilisation in all experiments by 5 to 10%.

Bergman⁴ showed that blood glucose concentration in sheep is closely related to turnover rate of glucose. This implies that the rate of glucose utilisation is dependent on sufficiently high blood glucose levels. It can be assumed that such elevated blood glucose levels also stimulate insulin secretion⁵ and thereby amino acid transfer into cells. These findings would offer an explanation for the growth response to antibiotics in ruminants, which seems, according to general experience, more pronounced when diets with high roughage content are fed. Such diets tend to lead to a relative "glucose deficiency" not

Fig. 1 Effect of Diumycin on growth and blood glucose. Twelve female, individually fed calves (starting weight 68 kg) were subjected to each treatment. Concentrates and hay were given *ad libitum*. With no Diumycin in the feed (●), the average daily gain in body weight was 709 g. With 10 p.p.m. (□) of Diumycin in the feed the average daily gain was 823 g. The arrow indicates the withdrawal of milk replacer.

Fig. 2 Relationship between the level of Diumycin in the feed, growth and blood glucose. Sixteen female, individually fed calves (starting weight 61 kg) were subjected to each treatment. Concentrates were fed *ad libitum* but hay was restricted. With no Diumycin in the feed (○), the average daily gain in body-weight was 680 g; with 5 p.p.m. (△). Diumycin in the feed the gain was 748 g and with 10 p.p.m. (□) in the feed the gain was 743 g. The arrow indicates the withdrawal of milk replacer.

only by supplying less preformed glucose, but also by favouring formation of acetic acid rather than propionic acid, which is the main precursor of glucose in ruminants.

We conclude that nutritive antibiotic action in the ruminant is related to elevated blood glucose, which may result from either increased rumen synthesis of propionic acid or decreased degradation of starch and sugars in the rumen.

Structural Difference between Luminal and Lateral Plasmalemma in Pancreatic Acinar Cells

THE acinar cells of the pancreas, as well as other exocrine protein secreting cells, are highly polarised. Release of secretion products, which occurs by exocytosis (fusion of the secretory granule membrane with the plasmalemma (PM) followed by opening at the point of fusion¹, is limited to the restricted portion of the cell surface facing the secretory lumen. It is still unclear whether this selective localisation of discharge depends on the specific properties of the luminal portion of the PM. Studies carried out in other cell systems have indeed revealed that regions of the PM where specialised functions are located can exhibit distinct characteristics²⁻⁵. But in the pancreas a comparative analysis of the secretory portion of the PM relative to the non-secretory portion has never been reported. By the use of freeze-fracture we have now observed that the luminal PM is different in structure from the remainder of the PM. Rather it is reminiscent of the membrane with which it is functionally associated, the membrane of the zymogen granule (ZG).

MORRIS COLLEGE

Male albino guinea pigs were starved for 24 h and then killed by a blow on the head. Small pancreas tissue fragments were fixed for 30 min in 1.5% glutaraldehyde and 1% formaldehyde, freshly prepared from paraformaldehyde, in phosphate buffer, pH 7.3, then infiltrated for 3 h in 30% glycerol in 120 mM phosphate buffer, pH 7.3. Samples were frozen by immersion in Freon 22, cooled to -150°C in liquid nitrogen, then freeze-fractured according to the method of Moor and Müllethaler⁶ in a Balzers freeze-etching device. Fracturing temperature was -115°C . Platinum-carbon replicas were washed in Na hypochlorite to remove organic material, then in distilled water and recovered on 200 mesh copper grids. The replicas were examined in a Philips EM 200 electron microscope.

Large areas of both the luminal and lateral PM were exposed by cleavage. Sheets of apical PM are easily identified by the presence of a surrounding continuous network of thread-like structures which, from previous studies, are known to correspond to tight junctions⁷ and by the occurrence of rounded elevations or depressions and finger-shaped structures which are identified as cross-sectioned and tangentially exposed microvilli.

It is well known that the PM is a highly asymmetrical structure⁸. In general, after cleavage, most of the particles are associated with the half of the membrane left frozen to the cytoplasm (the A face). The face of the half membrane left frozen to the extracellular space (the B face) bears fewer particles per unit area. In pancreatic acinar cells the typical A face pattern can be found only in the basal and lateral portions of the PM (including the regions close to the tight junctions and within the chambers delimited by their network). But over the entire luminal area there are far fewer particles per unit area of the A face (Fig. 1). The transition is very sharp across the inner continuous line of the tight junction delimiting the lumen, as can be seen when the fracture plane runs continuously from the lateral regions through the junctional complex to the luminal area (Fig. 1a). On the B face the number of particles is always very small, with no clear difference between the luminal and the lateral portions of the PM (Fig. 1b).

The limiting membranes of the ZG stored within the cells bear many fewer particles per unit area than the membranes of the other cytoplasmic organelles. The distribution is again asymmetrical, with more particles in the half membrane left frozen to the surrounding cytoplasm (A face) (Fig. 1, inserts). Hence, if we look at the particle patterns, the B face of the ZG

membrane resembles the B face of the whole PM while the A face of the ZG membrane looks like the luminal PM A face. Since during exocytosis the A leaflet of the ZG membrane becomes continuous with the A leaflet of the luminal PM and the same occurs with the two B leaflets, we have been led to postulate that the morphological similarity is more than a casual event and might be the expression of a similar biochemical composition. Indeed, our previous studies on isolated cellular membranes of the guinea pig pancreas have shown that the ZG membrane and the PM are similar in lipid composition⁹. Also, at least some of the polypeptides present in the ZG membranes seem to be present also in the PM preparations, even if the polypeptide composition of the latter fraction is much more complex¹⁰. Our PM preparations, however, represent portions of the entire surface, whereas a meaningful comparison should be made with the luminal portion only, which accounts for a small proportion of the total fraction¹¹.

It might be argued that the peculiar structure of the luminal PM could only depend on the continuous insertion of ZG membrane patches. Since ZG membranes contain few particles such insertion could result in a 'dilution' of the typical PM particle density. But if this were the case, one would expect to find, at least in some cells, an uneven distribution of particles over the luminal A face (ranging from areas similar to ZG membranes to areas of the typical PM type) and no sharp transition at the level of the tight junction. Our results were exactly opposite to this. Furthermore, in our experiments the animals were starved and in these conditions the rate of discharge of ZG is known to be very low. We believe therefore that the peculiar structure that we have observed is probably intrinsic to the luminal PM and could be maintained by a selective restriction in membrane mixing occurring in the PM at the level of the tight junction.

Recent turnover experiments in which ZG membrane proteins have found to have much longer half lives relative to the secretory proteins are consistent with the idea that ZG membranes can be reutilised in many secretory cycles¹². Thus, once fused with the luminal PM, they should be somehow reinternalised, either as discrete macromolecules or as intact membrane patches, to be reassembled within the cell. In agreement with this conclusion it has been previously observed that a population of vesicles, possibly retrieved from the luminal PM, appears in pancreatic acinar cells following stimulation of secretion¹³. These results, together with those we report, make it tempting to suggest that the ZG membranes and the luminal portion of the PM might be part of a unique pool of membranes which are continuously shuttled backward and forward between the newly formed ZG and the luminal surface. It is interesting that also in other cellular systems (the toad bladder epithelium and the endothelia^{5,14}) the vesicles known to be able to specific interaction (fusion-fission) with the PM have particle pattern and polarity similar to the portion of PM with which they interact. It therefore seems possible that the phenomena which are at the basis of our observations might not be limited to secretory cells but have a more general occurrence.

We acknowledge the technical assistance of Mr P. Tinelli and Mr F. Crippa. We thank Dr F. Clementi for discussions and suggestions.

Heterotransplantation of human foetal organs to the mouse mutant *nude*

THE mouse mutant *nude* displays thymic aplasia which entails a defect in cell-mediated immune responses. This immune deficiency has been demonstrated by transplantation of normal allogeneic skin and heterogeneic skin from mammalian donors including man, and from avian and reptilian donors¹. The *nude* mutant also accepts transplants of many human malignant tumours, including adenocarcinoma of the colon and rectum, malignant melanoma, squamous cell carcinoma and Burkitt's lymphoma (refs 2-4 and C. O. P., unpublished results). We report here the results of experiments involving transplantation of human foetal organs to the *nude* mouse.

Donors were five 14- to 22-week-old human foetuses, the results of pregnancies terminated by Caesarian *sectio parva*. The reasons for termination are given in Table 1 together with the gestational age and sex. All foetuses were considered normal. Immediately after the section, foetal thymus, lung, myocardium, pancreas, adrenal, kidney, spleen, liver, testis, ovary and spinal cord were transplanted in *nude* mice. The inocula measured about 2 × 1.5 × 1.5 mm and were implanted subcutaneously in the lateral abdominal wall.

Table 1 Reasons for Termination of Pregnancies, Gestational Age and Sex of Human Donor Foetuses

Experiment No.	Indications for Caesarian <i>sectio parva</i>	Gestational age (week)	Sex
1	Social	16	m
2	Neurosis neurasteniformis	14	m
3	Rubella	20	f
4	Social	18	m
5	Rubella	22	f

Recipient *nudes* were the 6-week-old progeny of both sexes of the sixth and seventh cycle of backcross mating with Balb/c mice. Breeding was conducted at the Pathological Anatomical Institute, Kommunehospitalet, Copenhagen¹. Testicular and ovarian transplants were restricted to the corresponding sex, but otherwise no account was taken with sex. Animals were observed daily and transplant growth was noted until death or killing.

Tissues were taken from the implantation sites for histological studies. All were fixed in neutral formalin (apart from testis and ovary tissue where Cleland's fixative was used) embedded in paraffin wax, and 7 µm sections were cut and stained with haematoxylin and eosin and van Gieson-Hansen. Four µm serial sections of testis and ovary transplants were stained with iron haematoxylin using Rowley and Heller's method⁵. Observation times after transplantation and the results are given in Table 2.

Table 2 Results of Transplantation of Human Foetal Tissue to *Nude* Mice

Inoculated tissue	Observation (d)	Fate of graft (accepted/total)
Thymus	19-59	7/13
Lung	13-64	10/12
Myocardium	54-60	0/2
Pancreas	64	1/1
Adrenal	17-39	3/12
Kidney	18-36	2/4
Spleen	21-48	0/7
Liver	17-57	0/10
Testis	23-57	3/5
Ovary	5-33	2/4
Spinal cord	21-57	0/2

Macroscopically, lung, thymus, testis and ovary transplants progressively increased in size. Lung transplant growth was most marked, maximally to 6 × 8 × 9 mm. At autopsy the accepted transplants were well defined, apparently encapsulated in the subcutaneous space, and richly vascularised by regional vessels. When transplants did not take, only sparse yellowish tissue remnants were found. Microscopic examination of accepted organ transplants showed these to be richly supplied by host vessels. There was only a minimal inflammatory reaction consisting of a few mononuclear cells. The histological appearance of these organs was as follows.

The thymus was of normal lobular appearance with some differentiation of cortex and medulla. The epithelial elements in the medulla were further differentiated so that number of Hassall's corpuscles were readily identifiable. The cortical vessels were sheathed by epithelial cells, and the cortex otherwise dominated by lymphocytes with a moderate number of mitotic figures. Reticulum cells and histiocytes were in normal concentrations. Compared with the donor material, the distinction between cortex and medulla was less apparent. An increase in the number of Hassall's corpuscles was noted, but these were of normal appearance (Fig. 1).

The lung showed a domination of markedly dilated alveolar-like structures with a much flattened epithelium. Ducts, the primitive bronchial structures, were clearly seen passing from the alveolar formations. These were lined by one layer of ciliated columnar cells with nuclei placed towards the lumina. Smooth muscle and isolated immature cartilaginous tissue in a mesenchymal stroma were seen in the duct wall together with normal vessels. By comparison with original transplants there was a very marked reduction in mesenchymal tissue elements. (Fig. 2a-c).

Fig. 1 Human foetal thymus 59 d after transplantation to *nude* mouse. Hassall's corpuscle surrounded by lymphocytes, histiocytes and reticulum cells × 270. Haematoxylin and eosin (HE).

Fig. 2 *a*, Human foetal lung tissue before transplantation (experiment 1). Primitive bronchial structures (ducts) in abundant mesenchymal stroma $\times 270$. *b*, Low power view of same lung tissue 36 d after inoculation in *nude* mouse. The transplant is situated in the subcutaneous space between skin (top) and abdominal muscle layer (bottom). $\times 40$. (HE). *c*, Detail of *b* showing duct surrounded by alveolar-like structures. Note marked reduction in mesenchymal stroma. $\times 242$. (HE).

The pancreas was of normal lobular appearance. Normal acini and small ducts constituted the exocrine elements of the gland, and the islets of Langerhans were normally formed. The histological picture was in good accordance with donor material. In the adrenal, viable tissue comprised only cells of the adult or provisional zone. These were small with round chromatin-rich nuclei which filled most of the cell. The sparse cytoplasm contained few vacuoles. In the foetal zone there was extensive necrosis. No medullary tissue was seen (Fig. 3).

The recovered kidney tissue closely resembled the original transplant. Glomeruli were of variable size, but probably normal in number. Two or three vessel roots were seen with patent lumina and containing erythrocytes. The proportion of

mesangial tissue seemed to be as in the original implant. The visceral and parietal aspects of the Bowman capsules were covered with regular cylindrical epithelium. The capsular spaces seemed to be empty. Tubules were well preserved with an epithelium resembling that of the implant. The proportion of interstitial tissue was increased. This tissue was a loose, connective tissue with many vessels of normal appearance. (Fig. 4 *a, b*).

The general structure of the testis implant was preserved with interstitial tissue containing seminiferous tubules of normal size. The latter contained gonocytes and undifferentiated Sertoli cells. These cells could not be distinguished from normal foetal cells. Some of the interstitial cells resembled fibroblasts while others had some similarity to Leydig cells (Fig. 5).

The stroma of implanted ovaries was of normal appearance and contained a mixed population of oogonia and oocytes. No definite progression in the ovarian development could be demonstrated in the transplants when compared with histology of the tissue before implantation.

At the sites of spleen, liver, myocardium and nervous tissue implantation only necrotic tissue remnants were found with accumulations of macrophages.

Thus the study showed that many human foetal organs (thymus, lung, pancreas, adrenal, kidney, testis and ovary) can be successfully transplanted to the *nude* mouse. Histologically the structure of these organs was essentially preserved, and some development occurred. The appearance of the lung transplants needs a special comment. The dilated alveolar-like structures may be explained by secretion retention dependent on the ectopic lie and by a normal development and differentiation to alveolar-like structures with reduction of mesenchymal elements. This investigation was too small to give any explanation of why some transplants take and others do not, or have not so far.

Other *in vivo* models have been used for human organ transplantation: for example, the chorio-allantoic membrane in the fertilised chicken egg⁶, neonatal rodents⁷ and immunologically tolerant⁸ or immunosuppressed animals⁹. The study organ has generally been human skin, and takes have been achieved for varying periods.

This communication reports the first successful transplantation of human foetal organs to the *nude* mouse. The system seems to offer rich opportunities for the study of growth and differentiation of these organs. Of immediate further interest would be a study of the effects of hormones and carcinogens, as well as toxic, teratogenic, and infectious agents on foetal tissues thus transplanted. The special opportunities which heterotransplanted testicular and ovarian tissue offer will be discussed elsewhere¹⁰. Two important limiting factors need

Fig. 3 Human adrenal tissue 28 d after inoculation. Cells from the provisional zone are viable, whereas the foetal zone is necrotic. $\times 270$ (HE).

Fig. 4 a, Human foetal kidney (exp. 4) before inoculation. $\times 270$ (HE). b, Same tissue 36 d after inoculation in nude mouse. The primitive glomeruli and tubules closely resemble the donor material $\times 270$ (HE).

however to be mentioned. Donor material is not readily available, and the nude mouse is extremely prone to infection which even under good conventional conditions limits the nude lifespan to 4 or 5 months. We expect that exploitation of strict specific pathogen free or germ-free milieu will largely compensate for the latter difficulty¹.

Fig. 5 Human testicular tissue 36 d after implantation. Three seminiferous tubules containing Sertoli cells (S) and gonocytes (G) are shown $\times 340$, iron haematoxylin.

Efferent control of cricket giant fibres

THE central nervous system not only receives sensory input, but also controls the nature of that input. Efferent control of sensory pathways was suggested on the basis of behavioural experiments by von Holst and Mittelstaedt¹ and by Sperry², who called the postulated mechanism efference copy and corollary discharge, respectively. They argued the need for an efferent system to compensate for the stimulation received during behaviour, and which would otherwise be interpreted as due to events occurring in the environment.

An early example of efferent control was the gamma system of vertebrate muscle spindles³, and since then several examples of control of sensory pathways at various points, from the primary receptors to deep within the central nervous system, have been described^{4,5}. But it has been difficult to show that efferent pathways carry efference copy or corollary discharge. We have now shown, using three experimental techniques, that two second order neurones in the house cricket, *Acheta domestica*—the lateral and medial giant interneurons (LGI and MGI)⁶⁻⁹, the largest axons in the abdominal connectives—are under efferent control. We have also shown that the control blocks impulses in these neurones, and that the efferent inhibition is operative in the behavioural circumstances that would result in self-stimulation.

Recordings were obtained from free-moving animals by securing a pair of 50 μ m wires around one connective, anterior to the terminal abdominal ganglion¹⁰. Each animal was tethered by the recording leads, in a 12 \times 12 inch arena with sand over the floor. The stimulus was a continuous 12 Hz sine wave contaminated by distortion in the output of the speaker.

Good control of stimulus parameters and clear identification of the LGI and MGI were achieved in restrained but minimally dissected crickets. After removal of the wings and the leg at the coxotrochanteral joint, each cricket was mounted ventral side up, and a flap of abdominal cuticle was

FIG. 1 Inhibition of giant fibres during running and grooming in a free-moving cricket with implanted electrodes (periods of running (a) and grooming (b) behaviour are marked with black bars). The animal was stimulated with 12 Hz tone which elicited giant fibre activity at each cycle; this activity was suppressed during episodes of behaviour.

removed. Silver wire electrodes surrounded by petroleum jelly recorded electrical activity in the two connectives independently.

Intracellular recordings were obtained from the dendrites of the MGI, as described elsewhere¹¹. Briefly, the animal was dissected from the dorsal side and the terminal ganglion was supported by a spoon-shaped holder; suction electrodes were attached to one abdominal connective and to the ipsilateral main leg nerve of the metathorax. A micropipette filled with Procion yellow¹² or potassium acetate was inserted through the sheath, and the neuropile was probed for the large dendrites of the MGI, which were identified by their responses to sensory stimulation and their electrical characteristics^{6,7,11}.

In free-moving preparations large spikes occurred with every cycle of the low frequency sound stimulus. During each bout of running the large units were silenced, although the stimulus continued unchanged (Fig. 1a). The inhibition was also correlated with other movements of the metathoracic legs, such as grooming (Fig. 1b). The experimenter's taped verbal account of the animal's behaviour is not a precise measure of the timing and specificity of the effect, but spike activity was monitored through an audio channel throughout each experiment and the results were unequivocal.

In restrained, minimally dissected preparations the LGI and MGI are reliably identifiable in the extracellular record. A touch to the head or thorax elicited running, that is vigorous waving of the leg stumps. In a quiescent animal, a tone pulse of 600 Hz and moderate intensity elicited a burst of spikes. The response was inhibited profoundly during running episodes (Fig. 2). On average, the response to strong stimuli (90 dB) was diminished less than the response to weaker stimuli (80 dB), but within this range of intensities the units were sometimes silenced completely.

In the restrained and highly dissected preparations used for intracellular recording, the MGI received inhibitory post-synaptic potentials (i.p.s.p.s.) during spontaneous bursts of spikes recorded from the ipsilateral metathoracic main leg nerve. During spontaneous motor activity, recordings from the dendrites of the MGI showed a hyperpolarisation of as much as 8 mV, which was maintained throughout the motor activity and sometimes extended beyond it (Fig. 3b). The MGI was often inhibited before the first observable motor spike. It has been suggested that efferent control of the lateral giant interneurone of crayfish is mediated by presynaptic inhibition¹². Many of our results might have been interpreted in a similar way since there was often a considerable decrease in excitatory end plate potential (e.p.s.p.) amplitude without obvious i.p.s.p.s. In other cases, however, i.p.s.p.s. were clearly recorded in the MGI dendrite, thus excluding a purely presynaptic mechanism. We could not demonstrate any direct correlation between unitary i.p.s.p.s. and motor nerve spikes. We conclude that the linkage between motor neurone activity and MGI inhibition is indirect, possibly provided by

an inhibitory neurone which receives excitatory input in common with the motor neurones.

The source of the descending inhibition was localised by selective cutting of interganglionic connectives. Inhibition was blocked by bilateral connective section anywhere between the third thoracic and terminal abdominal ganglia, but not anterior to the metathoracic ganglion. Thus the metathoracic ganglion is sufficient to produce inhibition. The possibility of additional inhibitory influences descending from more rostral centres remains open.

Most inhibitory influence on the LGI and MGI was abolished by sectioning of the connective ipsilateral to the axon of interest, while cutting the contralateral connective had a small effect. In contrast, the smaller ascending giant interneurons which fire tonically receive their inhibitory control equally from the two connectives. This pattern of connections correlates well with the pattern of sensory connections of the same neurones and with their dendritic field shapes: the LGI and MGI receive virtually exclusively ipsilateral excitatory input from the cerci and have unilaterally distributed dendrites, while the smaller, tonically active units receive bilateral input and have bilaterally distributed dendrites⁷.

Another inhibitory effect, which was completely independent of the thoracic centres, was also observed. When stimulated to run by a puff of wind aimed at the body, a reduction in the response to a standard tone could be detected even after severing all connections between the terminal ganglion and the remainder of the nervous system. This reduction in response might be due to lingering air movements or inhibitory circuits within the terminal ganglion.

Although the exact function of the giant fibres in controlling evasive behaviour has not been determined⁹, powerful stimulation of cercal receptors, which excites the giant fibres

FIG. 2 Response of the two largest interneurons (LGI and MGI) to tones during periods of motor activity and rest. Each dot indicates the occurrence of a single spike, each row a single trial. For each stimulus intensity, indicated in the upper left hand corner, fifteen repetitions during touch-elicited running (above) and fifteen repetitions during rest (below) are shown.

FIG. 3 Inhibition of the MGI during motor activity. (a) demonstrates that spikes recorded from the impaled neuron (top trace) are correlated 1:1 with spikes recorded extracellularly from the connective anterior to the terminal ganglion (lower trace). (b) shows that a spontaneous burst of motor activity (bottom trace) is correlated with a hyperpolarisation of the MGI (top trace) and a decrease in tonic activity in other giant fibres recorded extracellularly (middle trace). Calibrations: vertical *a*, upper, 40 mV; *b*, upper, 8 mV; horizontal *a*, 12 ms; *b*, 200 ms.

as a group, often elicits escape jumps. Therefore, excitation of the cercal receptors such as may occur during grooming or locomotion, might elicit evasive behaviour which would be inappropriate because the stimulus resulted from the animal's own behaviour and not from environmental events. On the other hand, escape is a high priority behaviour, and is not likely to be blocked completely during grooming or casual locomotion. In fact, the efferent inhibition can be overcome by strong stimulation (Fig. 2). Thus it seems that these neurones' thresholds are modulated to preserve the significance of their spike activity during behaviour. This could be interpreted as a simple example of the functioning of efference copy or corollary discharge.

C. H. F. Rowell made useful comments on the manuscript. This investigation was supported by a biomedical sciences support grant (to R. K. M.) and a research grant (to J. P.), both from the National Institutes of Health.

Chloride-related Depolarisation of Crayfish Muscle Membrane Induced by L-Glutamate

THE action of L-glutamate is localised at the junctional region of the muscle membrane in Crustacea and mimics that of the neurotransmitter in various characteristics. It is therefore possible that L-glutamate is the excitatory transmitter of the crustacean neuromuscular junction^{1,2}.

The excitatory junctional potential (e.j.p.) and glutamate potential induced by iontophoretic application of L-glutamate require Na but not Cl (refs 3, 4), but Cl was essential for depolarisation induced by the drug in the present experimental conditions.

The experiments were carried out on the opener muscle of an isolated walking leg of the crayfish (*Cambarus clarkii*). The experimental procedures, conditions and physiological solution were almost the same as those described elsewhere⁵. Propionate (Tokyo Kasei Kogyo, Co.) was used as the non-permeable and inert ion⁶⁻⁸ to replace all the Cl in the modified Van Harreveld's solution. To determine changes in resting potential, a coarse microelectrode filled with 3 M KCl was used as an indifferent electrode. Experiments were usually performed at room temperature (21°–22° C).

When L-glutamate (10⁻⁴ M) was added to normal medium, the muscle membrane was depolarised by about 10 mV after 1 min, and began to repolarise but stayed at a depolarised level a few minutes later, while the e.j.p.s. gradually disappeared at this time (Fig. 1*Aa*). On the other hand, when Cl was removed from the medium, the membrane was not depolarised but hyperpolarised by the drug (Fig. 1*Ab*). The large e.j.p. attained after the removal of Cl abruptly disappeared after the drug application, in contrast to the decreasing disappearance of the e.j.p. in normal medium (Fig. 1*Aa*).

This suggests that Cl is required for glutamate depolarisation in this case, provided that propionate replaced with Cl is inert to the postsynaptic membrane (Fig. 1*Aa,b*). The lack of glutamate response in Fig. 1*b*, however, may not be due to the accelerated desensitisation, because when glutamate was quickly added by iontophoretic application, the drug could

Fig. 1 Effect of chloride withdrawal on L-glutamate-induced depolarisation and input resistance. *A*: Excitatory axon was stimulated by a train of 8 impulses at 90 s⁻¹ every 6 s, and the e.j.p.s. were displayed with a pen-writing recorder. The drug was added at the downward arrow by bath application and removed at the upward arrow. Calibration bars given for *A* and *B* are 1 min and 5 mV in all cases. *a*, Normal medium; *b*, 15 min after Cl removal. *B*: Two microelectrodes, one for recording and the other for passing current, were inserted into the middle of a muscle fibre. Electrotonic potential was produced by passing a current pulse of 2×10^{-8} A across the muscle membrane. *C*: L-Glutamate was applied iontophoretically at a junctional region after Takeuchi and Takeuchi². *a*, In normal solution; *b*, during withdrawal of Cl; *c*, after returning to the normal solution.

Fig. 2 Effects of L-glutamate on resting potential and inhibitory junctional potentials. The resting potential was monitored with a pen-writing recorder and the i.j.p.s that were induced by stimulating the inhibitory axon with a train of 8 impulses at 90 s^{-1} were displayed at each arrow by oscillographic means. Vertical bar at arrow 1 shows 1 mV for i.j.p., but 2 mV for a dotted i.j.p. The medium was perfused with a Cl-free solution at the upper bar and the drug was added at the lower bar by perfusing a preparation with a solution containing the drug. At arrows 7, 8 and 9, the same as arrows 3, 4 and 5 was repeatable, but 1 h after the Cl removal the hyperpolarising 'i.j.p.' was not observed further after drug application.

not produce any potential with Cl removal (Fig. 1C). This mode of drug action differed from that previously reported and that of the neurotransmitter²⁻⁴. There should therefore be another site of action for L-glutamate at which Cl is playing an essential role.

Effective resistance increased with depolarisation after the drug application (Fig. 1Ba). L-Glutamate, however, produced neither a depolarisation nor an increase in effective resistance after Cl removal (Fig. 1Bc). A simple interpretation of these facts is that Cl may carry all the depolarising current induced by L-glutamate without any considerable conductance increase, although this is rather complex because of the underlying non-linear relationship between the current and the voltage^{9,10}. Since the drug depolarised the membrane well beyond the Cl potential (Fig. 1Aa) that is usually found close to the resting potential¹¹⁻¹³, this amount of depolarisation cannot be brought about by an increase of Cl conductance alone, if at all. The Cl therefore must be 'pumped out' against an electrochemical gradient in this case. The experiments shown in Figs 2 and 3 may support this theory, although a possibility that Cl is indispensable for the depolarisation induced by other ions is not completely excluded.

With Cl removal the membrane potential was largely depolarised but began to repolarise after a few minutes (Fig. 2), while a depolarising i.j.p. induced by repetitive stimulation of the inhibitory axon (arrow 1) disappeared several minutes later (arrow 2). In this condition, L-glutamate still produced the depolarisation, presumably because some amount of internal Cl remained. About 2 min after drug application, the membrane began to repolarise and became hyperpolarised beyond the original level. During repolarisation, a large hyperpolarising 'i.j.p.' appeared in spite of a Cl-deficient condition as shown at arrow 3. The 'i.j.p.' became smaller in size with the hyperpolarisation of the membrane and disappeared at arrow 4. Since the i.j.p. is induced by selective conductance increase of Cl (refs 11, 14), this experimental result indicates that a concentration gradient of the ion across the membrane has become high at least at the synaptic region after the drug application. The greater amount of external Cl beyond that predicted from the Nernst equation should be pumped out and retained there for a while. A considerable amount of Cl can be expected to remain inside the muscle fibre even in Cl-free medium¹⁴⁻¹⁶.

When L-glutamate was removed from the medium, the i.j.p. began to go positive (arrow 5) and then diminished at arrow 6, suggesting that the amount of external Cl 'pumped out' decreased after withdrawal of the drug. Although the possibility that K or propionate may become permeable when the inhibitory synapses work under the glutamate action has not been excluded, this experimental fact can more reasonably be accounted for by the stimulating action of the drug for the 'Cl-pump' at the junctional region than by the interaction between the drugs.

When the temperature of a preparation was varied by perfusing it with cold or warm solution, glutamate potential altered greatly depending on the temperature (Fig. 3). With cooling, the potential became smaller and finally disappeared when cooled below 15°C in this preparation. The potential reappeared and was restored to original size by warming the muscle fibre. The peak time of these potentials showed little change in the course of this procedure^{6,17,18}. Essentially the same result was obtained in a case where the drug was applied by the perfusing procedure. The temperature at which the glutamate potential disappeared depended on the preparation and the quantity of the applied drug, ranging from 15° – 19°C .

From these experimental results it seems likely that the Cl-related depolarisation produced by L-glutamate was brought about by an 'electrogenic Cl pump', at least in part, which might be loosely coupled with the 'Na pump'. The slow hyperpolarisation after the drug application and the depolarisation after removing it in Fig. 2 suggest a hyperpolarising action of the drug in addition to the depolarising action. The depolarising action would be dominant in a normal medium. In this connection, it is interesting that this type of active transport has been found in various tissues of many kinds of animals¹⁹⁻²⁴. It is also likely that this type of activity may prove to be of importance in the control of the synaptic activities or the long-term reaction in the muscle^{25,26}.

Fig. 3 Effect of temperature on glutamate potential. L-Glutamate was applied iontophoretically at a junctional region every 12 s. The preparation was perfused with cold or warm solution and its temperature was read on a thermometer inserted close to the preparation in the bath. A: a, at 21°C ; b, below 15°C ; c, after rewarming the preparation to 21°C . B: Relative amplitude of the glutamate potentials plotted against temperature. Arrows show experimental procedure.

Some dissociated characteristics between the e.j.p. and the glutamate potential should be subjected to further investigation so that L-glutamate may obtain a definite qualification as a candidate for the excitatory transmitter at the crustacean neuromuscular junction.

I thank Professor M. Otsuka for his encouraging this study.

Extracellular Currents from Frog Photoreceptors

EVIDENCE has been presented to show that dark current flows around vertebrate photoreceptors^{1,2}. The outer limb is a sink for this current; the remainder of the receptor is a source. The effect of light is to reduce the current by increasing the resistance of the outer limb membrane^{3,4}. Some authors have, however, suggested complications to this hypothesis^{5,6}. The problem was therefore reinvestigated for the frog, *Rana esculenta*.

Our methods were modelled on those described by Hagins *et al.*^{1,2}, but instead of retinal slices, whole retinas were mounted on a holder consisting of two perspex plates hinged by a collodion film. When this holder was folded, the receptor edge of the retina protruded through a 1 mm long slit in the collodion. The holder was placed between two pools of Ringer on a microscope slide, and the receptor edge could be viewed by infrared microscopy. The edge was moved onto an array of

microelectrodes and recordings were made of potential differences between electrode pairs. Changes in potential were observed when there was a change of electrode position relative to the retina, or when the retina was stimulated. Stimulation consisted of constant current pulses applied across the edge followed by light flashes perpendicularly incident to the receptor axes.

The records of Fig. 1 were obtained from two electrodes on a line at right angles to the edge. One electrode remained fixed, as the edge was advanced upon it; the other was always adjusted to a given reference position at the receptor tips. The bathing medium contained aspartate ions to simplify the potentials⁷. Little response to light was seen when the retinal electrode was 30 μ m deep (Fig. 1a). At 45 μ m it registered a small response which long outlasted the stimulus (Fig. 1b). This region of the retina contains mostly rod outer limbs. At 60 μ m and beyond (Fig. 1c-g) the electrode was among both rods and cones and recorded two components, the prolonged one previously seen and a fast one with a time course matching the stimulus. Individually the two components resemble intracellularly recorded rod and cone receptor potentials⁸.

The relationship between dark voltage and photovoltage was examined in the experiments of Fig. 2. The electrodes remained

Fig. 1 Average voltages across receptor layer due to current pulses and responses to light flashes, repeated two to four times at each depth. a, 0–30 μ m; b, 0–45 μ m; c, 0–60 μ m; d, 0–75 μ m; e, 0–90 μ m; f, 0–105 μ m; g, 0–120 μ m. 0 μ m corresponds to the receptor tips. Calibration deflections mark the occurrence of current pulses (duration: 240 ms), and light flashes (1 s). The amplitude of the deflections corresponds to 15.6 μ V (a–c), 31.3 μ V (d), and 62.5 μ V (e–g). Current pulses were 5.5 μ A (a–e) and 1.7 μ A (f–g). Upward deflection recorded when current flowed receptor to ganglion side. Light flashes: 561 nm, 3.7×10^{13} $h\nu$ cm^{-2} s^{-1} , incident perpendicularly to the receptor axes. This light intensity produced a nearly saturated cone response but had no observable effect on the rod response when repeated at intervals of more than 40 s. Bandpass: 0–16 Hz. Electrode tips: about 2 μ m, 8 M Ω , filled with Ringer. Ringer: NaCl 72, KCl 1.8, CaCl₂ 0.1, MgSO₄ 0.1, NaH₂PO₄ 2.5, Na₂HPO₄ 10, glucose 10, monosodium aspartate 10 mmol l^{-1} (pH=7.2–7.3).

Fig. 2 Continuous records showing responses to light flashes and DC changes accompanying changes in the position of the electrodes relative to the retina. Position of electrode tips, B and A, before movement and direction of movement of the retinal edge is indicated to the right of each record. Current pulses flowing receptor to ganglion side precede the light flashes and produce voltage 'spikes'. Downward deflection corresponds to positivity of A. Light flashes: 1 s, 561 nm, 3.7×10^{10} $\text{h}\nu \text{ cm}^{-2} \text{ s}^{-1}$. Horizontal lines mark the duration of the flashes and of the movements. The light intensity saturated the rod response without eliciting any noticeable cone activity. Bandpass: 0–1.6 Hz. This severe filtering lengthens the rise time of the rod response but has been shown not to affect its maximum amplitude. Electrode tips: 1–3 μm , 6–16 $\text{m}\Omega$, filled with Ringer. *a*, A changes position, 0–45 μm from receptor tips. Ringer: see Fig. 1 except 82 mmol l^{-1} NaCl and no aspartate. *b*, A changes position 45–0 μm . Ringer: see Fig. 1 except 10 mmol l^{-1} monosodium glutamate instead of aspartate.

stationary throughout and the edge was moved so that one electrode (A) entered the retina (Fig. 2*a*) or came out of it (Fig. 2*b*) while the other (B) was always outside. For currents originating in the retina, it was as if B always remained at the receptor tips, since within experimental error the region outside the retina was isopotential with the edge. The results shown are typical of more than seventy experiments, some performed with standard Ringer (such as Fig. 2*a*), some with aspartate or glutamate Ringer (such as Fig. 2*b*). They represent the potential recorded by B minus the potential recorded by A (V_{BA}). Entry of the electrode into the outermost 45 μm of the retina always produced a downward shift in the DC level (A goes positive relative to B) followed by the appearance of upward-going photoresponses, the amplitudes of which were never greater than the shift. When the electrode came out, there was an upward DC shift and the responses disappeared.

Two types of effect were seen when movements of the edge brought the retinal electrode to the region of the outer limiting membrane (about 90 μm). In about one third of the cases the retinal electrode recorded increasing positivity (usually between 50 and 100 μV), as would be expected if a dark current flowed from the inner regions of the receptors to their outer limbs. But in most cases, during the last stages of the movement the increase in positivity was interrupted by a negative shift of the DC level (a millivolt or more), but most of the shift proved transient. When the retina was moved off the electrodes, no big shifts were seen. Then about two thirds of the records showed a decrease in positivity of A matching the diminution of the photoresponses. Probably the big DC shifts arise when an electrode tip disrupts the tightly packed structure of the inner receptor layer⁹.

In a few experiments giant, unstable photoresponses, up to a millivolt, were recorded from electrodes reaching the region of the outer limiting membrane. But the voltages produced by current pulses flowing parallel to the receptor axes (in the so-called 'radial' direction) remained the size expected for the

electrode position, suggesting that the major part of the large photoresponses was not generated across the radial extracellular resistance. Similar giant responses have previously been obtained at various depths in the frog receptor layer¹⁰. They probably arise in much the same way as the large extracellular responses that can be recorded when an electrode contacts a single spinal motoneurone¹¹. In any case giant responses, like the transient DC shifts, mask the relationship between radial dark voltages and photovoltages, and both types of effect have been excluded from subsequent analysis.

Measurements of the potential difference between two points along the extracellular path parallel to the receptors, as in the experiments of Fig. 2, do not allow components from local sources and sinks to be distinguished from those of remoter origin. But if potential measurements are made at three successive points (C, B and A) in a radial direction, then given certain assumptions, the potential differences, V_{BA} and V_{CB} , can be used to compute I , the current arising or disappearing between C and A^{2,12}.

$$I = (i/v_{BA}) \{ V_{BA} - (v_{BA}/v_{CB}) \cdot V_{CB} \} \quad (1)$$

where v_{BA} and v_{CB} are the voltages generated by constant current pulses of magnitude i applied to flow along CA.

Equation (1) was used to determine photocurrents and dark currents from the photovoltages shown in Fig. 1 and from the corresponding dark voltage changes (not shown) produced by changes in electrode position. The results can be seen in Fig. 3.

Consider first the leading edge of the photocurrent. About 680 current units were generated in the layer 30–60 μm deep, while about 370 disappeared in the layer 60–90 μm , and 420 in the layer 90–120 μm . If about 110 units were produced in the layer 0–30 μm but could not be detected owing to the

Fig. 3 Current sources and sinks 30–120 μm from receptor tips. Experimental details: see legend to Fig. 1. The dark voltage changes for each 15 μm change of electrode position were measured directly. The voltages across each 15 μm layer due to current pulses and photoresponses were obtained by subtracting the successive records of Fig. 1 from each other. The potential differences across two adjacent 15 μm layers were scaled to compensate for resistance differences between the layers, subtracted from each other and converted to currents according to equation (1). Currents at three depths in the receptor layer are shown: *a*, outer limb region, 30–60 μm ; *b*, inner limb and myoid, 60–90 μm ; *c*, nucleus and synaptic region, 90–120 μm . For a given depth the dark current changes are compared with the photoresponses plotted on the same scale. The scale is indicated in arbitrary current units to the right of the photoresponses. Arbitrary current units are used because of problems in accurately defining the geometry of the retinal edge. The area of the exposed edge was of the order of 1 mm^2 . The dotted lines indicate the dark current before and after the retinal movement with its transient disturbances. Upward shifts represent current sources, downward shifts sinks. Bandpass for dark current changes: 0–1.6 Hz; for photoresponses, 0–4 Hz.

low resistance of the layer, all the photocurrent is accounted for and this must have arisen from the receptors, since up to about 90 μm no other cells are present. Likewise the dark current up to 90 μm can only have originated in the receptors. Its magnitude is in agreement with that of the photocurrent but is opposite in sign. Such a result provides evidence for the view that receptor photocurrents represent reductions of dark current, at least in the aspartate-treated retina.

For the layer 90–120 μm , there is a discrepancy between the size of the dark current actually observed and that needed from the layer to balance the sinks in the outer limbs. This implies that the layer contains not only receptor sources of dark current but also non-receptor sinks balanced by sources still deeper in the retina. Non-receptor dark currents account for a further discrepancy in Fig. 3c. Thus the net dark current source (receptor source + non-receptor sink) is smaller than the leading edge of the photocurrent (receptor alone). In other experiments, sinks of dark current in the inner receptor layer were even more pronounced, especially if no aspartate was added to the Ringer solution.

Figure 3 shows that, in addition to non-receptor dark currents in the innermost receptor layer, there are non-receptor photocurrents. The response waveforms of Fig. 3a and b match each other but are different from that of Fig. 3c. The result is consistent with the idea that there is a source of photocurrent in the layer of Fig. 3c, which develops slowly and reaches its peak after the cone and rod sinks have passed theirs. Possibly the source is in the outer ends of the Müller cells and gives rise to what has been called slow PIII in other vertebrates^{13,14}.

The existence of variable non-receptor sinks and sources of current in the receptor layer could perhaps explain some of the differences between the results of various studies. Further analyses of receptor function based on extracellular current measurements, especially those of the innermost receptor layer, will have to take non-receptor currents into account.

We thank Dr H.-G. Hartwig for information on the histology of the retina of *Rana esculenta*, and Mr W. Klein for technical assistance. The work was supported by the Deutsche Forschungsgemeinschaft.

Nematode growth factor

FREE-living nematodes, grown axenically in a chemically defined medium, might be of considerable interest as model systems for studying the fundamental aspects of genetics and differentiation of higher organisms.

Several species of free-living nematodes have been cultured serially in axenic media¹. Unfortunately, the chemically defined medium in current use, *Caenorhabditis briggsae* Maintenance Medium (CbMM)², does not support continuous growth unless supplemented with a 'growth factor' that can be derived from various biological sources. Conventional growth factor, thus prepared is proteinaceous and biologically highly active. When added as a supplement to the chemically defined medium it supports growth and maturation of the commonly used test organism *Caenorhabditis briggsae* within 3.5 (yeast ribosomes) to 5 d (heated liver extract) and continuous development for several generations, resulting in large final populations. The biological activity is associated with precipitate formation²⁻⁴.

It has been shown that *C. briggsae* has a nutritional requirement for sterols and haem^{5,6} that must be provided by the growth factor as they are not included in the basal medium. The proteinaceous portion of the growth factor has been substituted with some success by several commercially available proteins⁷. Substitution of the protein portion by heat stable material, such as glycogen, is also effective and as with growth factor, the biological activity is associated with the precipitated portion of the medium⁸.

Thus the current idea is that the growth factor consists of sterols, a haem moiety and organic material which might provide nutrient in the proper particulate form⁸.

I now wish to further clarify the nature of the growth factor for *C. briggsae*. My hypothesis is that growth factor contributes only two dietary essentials (sterols and haem) to the basal medium and that the third portion of the growth factor, whatever its chemical nature might be, serves only as a convenient vector of the haem component, which must be supplied in a particulate form. This implies that any material should be able to substitute for the third component of the growth factor, provided that it is not toxic to the nematodes, capable of 'carrying' an iron protoporphyrin complex, either by containing haem (such as a haem protein) or by binding an effective substitute (haemin chloride) and available to the nematodes in particulate form.

I have confirmed the growth promoting activity of ribosomes from yeast^{3,4} and *E. coli*⁵ and obtained the same activity with ribonucleoprotein (RNP) particles from bovine liver and HeLa cells. Pea seedling-RNP particles were unable to support growth but their activity was restored upon addition of haemin chloride. This supports the theory as most RNP particles washed only in low salt buffers, are easily contaminated with a haem protein (most probably a cytochrome⁹). *E. coli* ribosomes washed with 1 M salt are inactive, as could be expected.

In another set of experiments, several purified haem proteins were shown to be highly active when properly precipitated and added to the basal medium, containing sterols.

In a third series of experiments, iron binding proteins were allowed to interact with haemin chloride and then carefully precipitated and tested for their growth promoting activity. Some of these aggregates (especially ferritin-haemin and transferrin-haemin) proved to be as active as growth factors, derived from natural sources. Less specific iron-binding material as bovine serum albumin, albumen or conalbumin permits only limited development of *C. briggsae* with a longer generation time.

In the next set of experiments, the 'carrier' portion of the growth factor was substituted by the phospholipid lecithin. Egg lecithin was dispersed ultrasonically and haemin chloride

was allowed to interact with the phospholipid particles before addition to the basal medium containing sterols. It was expected that lecithin-haemin complexes might be formed (both are lipophilic), providing haemin in particulate form. Lecithin, supplied at a final concentration of 10 mg ml⁻¹ proved to be toxic. At concentrations of lecithin 1 mg ml⁻¹, haemin 50 µg ml⁻¹, *C. briggsae* developed continuously for several generations (Table 1).

Details of the above experiments will be given elsewhere. Although the results, reported here, do not allow definitive conclusions about the minimal chemical composition of the growth factor, they strongly support the hypothesis that the third component of growth factors, derived from natural sources, is primarily a matter of function (as a convenient

vector of haem) rather than of chemical structure. This suggests a trivial explanation for the failure of previous trials to elucidate the nature of the growth factor by means of sophisticated biochemical purification.

Conclusive proof that the iron protoporphyrin constituent in any particulate form is the active component in sterol supplemented medium, is given by the fact that a medium, composed of CbMM, sterols and precipitated haemin only, will support continuous growth and reproduction of *C. briggsae*. The experimental design was based on the apparent irreversibility of haemin precipitation in acid medium. When the haemin suspension is brought to pH 5-5.4, haemin does not redissolve appreciably. This pH range is still compatible with the acid pH tolerance of *C. briggsae*. The results of two experimental arrangements are represented in Table 2. In these experiments, growth, comparable with that supported by natural growth factors, has been obtained with concentrations of 25 to 100 µg haemin ml⁻¹. In general, there are only minor differences between the first and the second experiment, probably due to different pH and salt concentration (high concentration of salt and low pH are both unfavourable). Higher concentrations of haemin (200 µg ml⁻¹) inhibit fast growth in both experiments. Although the influence of salt cannot be excluded, indications from former experiments suggest that haemin itself becomes toxic at higher concentrations.

Up till now *C. briggsae* has been maintained axenically through 10 serial subcultures in this medium (haemin at 100 µg ml⁻¹; pH = 5.0) without change in growth rate. CbMM supplemented with sterols (50 µg ml), haemin chloride (50 µg ml⁻¹) and 3% v/v acetic acid (pH of final medium 3.5) supports also growth and maturation of the

TABLE 1 Biological activity of lecithin-haemin particles

Final concentration of supplement	Generation time (d)	Increase over inoculum after 28 d
Lecithin 10 mg ml ⁻¹

1.6	nm					

Mean values ± s.e. are given where possible. The number of replicates is given in brackets. Replicates were grouped in sets of four. Culture tubes containing 0.25 ml of medium were inoculated with three newly hatched larvae and incubated at 21-22°C. F₁ generation time is measured as the time from the incubation of these larvae to the production of larvae of the next generation. F₂ generation time is defined as the time required for two consecutive reproductive cycles. Media are evaluated further by the size of the population originating from the three initial larvae (counts of the cultures *in toto*). The size of the egg masses produced eventually after 21 d of growth provides an additional criterion. nd, Not determined; nm, not maturing.

* CbMM, containing sterols (50 µg ml⁻¹) was acidified with 1 N HCl to pH = 3.5 and subsequently supplemented with haemin chloride from a stock solution to obtain a final concentration of 400 µg ml⁻¹; in these conditions haemin precipitated immediately. This medium was then mixed with equal amounts of CbMM containing sterols (50 µg ml⁻¹) pH 7.67, thus giving a complete medium composed of CbMM, haemin at 200 µg ml⁻¹ and sterols at 50 µg ml⁻¹ with final pH of 5.0. This medium was then diluted serially with CbMM, pH 5.0, containing sterols (50 µg ml⁻¹) to obtain the concentrations of haemin indicated. This precipitation method implies the inclusion of high salt concentration in the medium.

† Haemin chloride was pipetted from stock solution into Hcl 0.01 N (pH = 2.0) to give a final concentration of 400 µg ml⁻¹. The suspension thus obtained, was then mixed with equal amounts of CbMM at twice the concentration, pH 5.9, containing sterols (100 µg ml⁻¹). The resulting complete medium is then composed of CbMM at 1× concentration, haemin chloride at 200 µg ml⁻¹ and sterols at 50 µg ml⁻¹ with final pH = 5.4. Serial dilutions were made from this medium with CbMM (containing sterols at 50 µg ml⁻¹) pH 5.4.

free-living nematode *Turbatrix aceti*. This organism has now already been maintained under aseptic conditions throughout nine serial subcultures.

Four main conclusions can be drawn from these findings. First, the growth factor for *C. briggsae* has been elucidated. This growth factor, it should be emphasised contributes only two dietary essential components to the basal medium: sterols and haem. Second, as the haem constituent can be substituted effectively by precipitated haemin chloride, a chemically fully defined medium for the axenic cultivation of *C. briggsae* is now available. Third, the fact that the haem component must be provided in particulate form to be efficient indicates strongly that it is taken up by phagocytosis. This hypothesis is now being checked. Fourth, it is quite conceivable and even probable that the elucidation of the growth factor for *C. briggsae*, may have significance far beyond the study of this single species, as suggested by the fact that supplements promoting growth of *C. briggsae* have also a stimulatory effect on growth of many other nematode species. In this respect, the successful axenic cultivation of *T. aceti* on a chemically fully defined medium may be highly significant.

I thank Professor A. Coomans, Professor E. Gillis and Professor W. Fiers for advice and criticism.

Depression of Morphine-seeking Behaviour by Dopamine Inhibition

MANY of the direct effects of morphine have been attributed to serotonergic mechanisms¹ or to the catecholamines^{2,3}. The role of brain monoamines in morphine's capacity as a behavioural reinforcer has only recently been explored^{4,5}, and it has been found that the catecholamine depletor α -methyl-*p*-tyrosine (AMT) blocks behavioural reinforcement by morphine. Our own work, started before these reports appeared, strongly suggests that dopamine is implicated in this blockade. To study morphine reward we adopted the technique of Beach⁶ which uses the acquisition and retention of a goal box preference and thereby minimises non-specific effects by experimental drugs on performance.

Sprague-Dawley male rats (180–300 g) were tested for pre-training preferences in a Y-maze with two contrasting boxes. Morphine dependence was induced by gradually increasing doses from 5 to 20 mg kg⁻¹ intraperitoneally twice daily, during 7 d. Training started with a saline injection in their home cages and an immediate forced run in the Y-maze to their preferred box where they were confined for 1 h. This was followed 20 min later by injection of 20 mg kg⁻¹ morphine and a forced-run to their non-preferred box and 1 h confinement therein. Training by forced runs was achieved by blocking off the opposite alley. We assume the rats learned to associate the effects of the injection with the response of running to the respective box. Sixteen free-choice trials (all barriers open) were presented on training days 15 and 16 (acquisition). Three weeks later, during which no treatment was administered (except see below), the rats were again tested with sixteen free choice trials (that is, 'relapse')⁶.

Our results show that the rats acquired and maintained a preference for their formerly non-preferred, morphine-rewarded box (group C-Mor, Fig. 1), in full agreement with Beach⁶. Choices of the latter were significantly greater than those of a group receiving saline alone (group C-Sal; $P < 0.01$), or compared with their own pretraining preference scores. No difference was found between these morphine-trained rats and parallel control groups receiving the carriers for the various modifying agents used below (Kruskal-Wallis analysis of variance⁷; d.f.=6; $P > 0.90$). These groups were therefore combined and are represented in Fig. 1 as C-Mor. All other P values were derived by the Mann-Whitney U test, two tailed⁷. That the learned preference was not an expression of avoidance of the 'withdrawal' box was shown by another control group run only to the preferred box. These rats selected the latter in 52 and 69% of their trials during the acquisition and relapse tests respectively, thus exhibiting no avoidance of this box. We, therefore, assume that the learned preferences are mediated by the euphoric and (or) the abstinence relieving components of morphine reinforcement^{8,9} rather than by avoidance of the opposite box, in line with the findings by Kumar¹⁰.

AMT, which has been repeatedly shown to deplete both noradrenaline and dopamine^{11–13}, was administered to another group of rats (80 mg kg⁻¹ intraperitoneally every 12 h) during morphine training. This treatment significantly depressed acquisition of a morphine-box preference ($P < 0.05$) and completely blocked relapse (Fig. 1). Initial choices of the morphine box were still greater than the C-Sal control group, indicating that the AMT only partially blocked morphine reinforcement. Catecholamine depletion by 6-hydroxy-dopamine (2 × 250 μ g intraventricularly, 2–4 d before training^{14–16}) in another group of twenty-one rats also significantly reduced acquisition and relapse similar to the AMT. Preferential depletion of serotonin by *p*-chlorophenylalanine¹⁷ (300 mg kg⁻¹ d⁻¹ for 3 d starting 5 d before morphine training and continued with 150 mg kg⁻¹ every other day during training) had no significant effect on preference scores in either test condition (Fig. 1).

Since AMT depletes both noradrenaline and dopamine, we tested to see whether one of these monoamines was more essential in mediating morphine reinforcement. Another group received the dopamine- β -hydroxylase inhibitor diethyldithiocarbamate (DETC), which depletes noradrenaline while dopamine levels remain unaffected or even increase¹⁸. DETC (400 mg kg⁻¹ injected daily 1.5 h before the morphine-reinforced trial) had no effect on morphine-box preferences (Fig. 1).

These data suggested that noradrenaline depletion was not critical in inhibiting morphine reinforcement. The role of dopamine was assessed in further groups treated with haloperidol which presumably blocks dopamine receptors¹⁹. Doses of 0.25, 0.5 and 1 mg kg⁻¹ haloperidol were administered 20 min before the daily morphine trials in separate groups. The 1 mg injections completely blocked morphine

Fig. 1 Proportion of morphine-box choices (or non-preferred box as defined by pre-training preference trials) during free-choice tests after indicated treatments. Number of rats in each group shown in parentheses. Open columns, acquisition; black columns, relapse. a, C-Sal; b, C-Mor; c, AMT; d, 6-hydroxydopamine; e, *p*-chlorophenylalanine; f, DETC; g, 1 mg kg⁻¹ haloperidol; h, 0.5 mg kg⁻¹ haloperidol; i, AMT plus 0.5 mg kg⁻¹ haloperidol.

reinforcement whereas 0.25 and 0.5 mg produced a significant reduction compared with group C-Mor ($P < 0.05$ in each case). Combining the treatment schedules for AMT and 0.5 mg haloperidol in an additional group, however, significantly reduced morphine-box choices below that of either treatment alone ($P < 0.02$ in each case) and did not differ from the 1 mg haloperidol group (Fig. 1).

The possibility that the AMT interfered with original learning or later memory of the morphine-seeking habit was examined in twelve rats trained with morphine while treated with AMT exactly as before, but were re-addicted to morphine 1 week before relapse testing. These animals showed a mild decrease in initial choice tests, but during relapse testing they selected the morphine-rewarded box 70% of the time, indicating that AMT did not impair learning or memory as compared with the original AMT group. Neither did administration of the modifying drugs alone have any effect on preference scores, as shown by two groups receiving AMT or haloperidol but no morphine ($N = 12$ and 11 respectively). The selection of the non-preferred box by the AMT group was 42% and 35% for the haloperidol group, and did not significantly differ from the scores of group C-Sal.

The data indicate that interference with dopamine activity, in contrast to noradrenaline and serotonin, effectively reduces the behaviourally reinforcing effects of morphine. Dopamine reward mechanisms recently implicated in intracranial self-stimulation²⁰ may be involved; however, since AMT reduces certain abstinence symptoms in the rat²¹ and also makes morphine aversive²², the possibility is raised that the reward value of morphine was diminished by these effects as well.

Appearance of Unusual Mitochondria in Rice Coleoptiles at Conditions of Secondary Anoxia

IN rice coleoptile cells mitochondria can be formed and preserved without any notable signs of destruction in the absence of molecular oxygen¹⁻³. In this, rice coleoptiles are strikingly different from other plant tissues, whose fine cell organisation is degraded during even a short-term anaerobiosis⁴⁻⁶. In the experiments mentioned, however¹⁻³, the rice seeds were grown from the very beginning under oxygen-free conditions. This excluded not only the possibility of functioning of mitochondria but, probably also, their normal formation. One could therefore suppose that such mitochondria as yeast promitochondria^{7,8} do not contain all the carriers of the respiratory chain and possess an enhanced resistance to anaerobiosis. High resistance of cell ultrastructure to anoxia could be, on the other hand, secured by intensive energy output through glycolysis.

With this hypothesis in mind, we were interested to find out whether the cells of coleoptiles would lack resistance to anoxia after their mitochondrial apparatus and the whole system of aerobic metabolism had already begun to function under conditions of normal oxygen supply. For this purpose rice (*Oryza sativa*) seeds were cultivated from the beginning with a normal air supply; only after 6 d of growth were the plants placed in anaerobic conditions for 24, 72 and 120 h.

After corresponding exposure to an atmosphere of nitrogen (99.997% purity) sections of the lower part of coleoptiles, of leaves and of roots (1-2 mm from the tip) were fixed by the method of Karnovsky⁹, embedded in Epon 812 and studied under a Tesla BS-513 electron microscope.

Destructive changes in mitochondria and other organelles in roots take place 1-3 d after they have been transferred to anaerobic conditions (Fig. 1a, b). This did not occur with coleoptiles. Their mitochondria and other organelles remained intact even after 120 h exposure to the nitrogen atmosphere. Some of the mitochondria remained intact, without any substantial changes in form and size, producing only more regularly ordered cristae. Other mitochondria

were transformed to large organelles with multilayer cristae. These organelles often had an irregular form (Fig. 1d). They

Fig. 1 Ultrastructure of mitochondria in cells of rice roots and coleoptiles in aerobic and anaerobic conditions. *a*, Root, 9 d after growth in aerobic conditions; *b*, root, 6 d of aerobic growth, then 3 d of growth in anaerobic conditions; *c*, coleoptile, 9 d of aerobic growth; *d*, coleoptile, 6 d of aerobic growth, then 5 d of growth in anaerobic conditions.

were 1.2–1.5 μm long whereas normal mitochondria are 0.5–0.6 μm long. The whole interior chamber of these mitochondria was filled with densely packed parallel cristae lying transversely to the long axis of the organelle.

Such mitochondria have not, as far as we know, been described yet in plant cells, for which layers of parallel cristae are not characteristic¹⁰. They are found in animal cells performing especially active work (cells of flight muscles in insects, myocardium of mammals)¹¹.

The appearance of these mitochondria, extremely unusual for plants, can hardly be attributed to the beginning of organelle degradation; it rather points to hypertrophy of the mitochondrial apparatus, arising in rice coleoptiles cells because of shortage in oxygen supply.

It is interesting that the mitochondria of leaves, which in contrast to coleoptiles do not start growing in the absence of O_2 revealed unexpectedly high resistance to anoxia: 3–5 d exposure of plants to nitrogen did not lead to their destruction.

High resistance of rice coleoptile cells to anaerobiosis is thus reflected not only in their ability to preserve mitochondrial apparatus when growing in strictly anaerobic conditions but also in especially active development of a number of mitochondrial cristae, possibly promoting more complete extraction of traces of oxygen from an environment which almost completely lacks it.

Dynamics of a brachiating siamang [*Hylobates (Symphalangus) syndactylus*]

THE slow brachiation which is characteristic of the siamang [*Hylobates (Symphalangus) syndactylus*] and to a lesser extent the smaller gibbons [*Hylobates (Hylobates) spp.*] is often described as pendulum-like^{1,2}. This comparison is apt because both the pendulum and the gibbons rotate about a fixed overhead fulcrum and make use of gravitational acceleration to effect movement. Beyond these basic observations, there have been few attempts to elucidate the mechanical aspects of this unique form of locomotion^{2,3}. Analysis of 16 mm cine films of free-ranging and captive siamangs and gibbons reveals details of their locomotor behaviour that can be interpreted as precise adaptations for maximising the forward momentum gained from pendular movement.

This study is based on excerpts from several thousand feet of 16 mm film of wild siamang in Pahang, Malaysia and 100

feet of 16 mm film of captive siamang and gibbons on semi-natural islands in the Zoo Negara, Malaysia. Film was shot by the author with a Beaulieu R16B camera at speeds between 24 and 64 f.p.s.

The slow brachiation of the siamang involves a repeated series of movements. A representative cycle (Fig. 1) can be analysed in terms of two distinct phases involving the coordinated movements of trunk and legs as well as arms. The downswing phase begins as the animal releases the trailing hand. As the body swings forward and down with the legs extended, the free forelimb remains extended and sweeps through an arc behind the body. The upswing begins as the siamang flexes both legs and the free forelimb; midway through the upswing the forelimb is extended for the next grasp. During a complete swing, the trunk rotates through approximately 180° about a vertical axis.

In this form of locomotion, there are three ways in which the siamang can maximise its forward momentum: by maximising the change in kinetic energy on the downswing; by minimising the loss of kinetic energy on the upswing, and by minimising any lateral components in its momentum. Analysis of the siamang's posture in different phases of a single swing shows how the postural changes are adapted to maximise forward momentum in all three ways.

The total kinetic energy, and hence the maximum velocity acquired during the downswing, is proportional to the distance between the animal's centre of mass and the centre of rotation (in this case its hand). In a frictionless system, the increase in kinetic energy is proportional to the change in height of the centre of mass during the downswing ($\frac{1}{2}mv^2 = \frac{1}{2}lw^2 = mg\Delta h$). For a given arc (α) of

rotation, the vertical displacement of the center of mass increases with the distance between the centre of mass and the centre of rotation [$\Delta h = \Delta r(\sin \alpha)$]. The siamang increases this distance on the downswing by extending its legs and its free arm (Fig. 1).

On the upswing, the siamang minimises the loss of momentum due to gravitational deceleration by approximating its centre of mass to the centre of rotation. This is accomplished by flexion of the legs and the free arm (Fig. 1). By decreasing the moment of inertia, this redistribution of mass should increase the rotational velocity of the siamang. This increase in velocity can be seen in stop-frame analysis.

For all of the kinetic energy acquired on the downswing to be converted into forward momentum, the centre of mass should travel in the same vertical plane as the centre of rotation. The siamang is able to limit lateral motion of the centre of mass between handholds by extensive rotation at the wrist, elbow, and shoulder (Fig. 1b).

In the motion of a simple pendulum all of the kinetic energy acquired on the downswing is subsequently changed to potential energy on the upswing so the pendulum retraces its path indefinitely. In a single swing of the siamang, the kinetic energy lost on the upswing is less than that acquired on the downswing because of the input of potential energy resulting from the redistribution of mass on the upswing. By the mechanisms described above, the siamang could theoretically acquire a net momentum from each swing.

In most forms of locomotion, an animal must exert a propulsive force against the environment in order to acquire a forward momentum. Although the brachiation of the siamang as described above probably involves some energy expenditure in supporting the body, only with the rotation of the trunk about the hand is there a suggestion of any work being performed against the superstrate. In instances when siamangs do not utilise this pumping mechanism, active rotation and brachial flexion appear to become more important. Further studies involving electromyography could possibly determine the nature of the muscular activity involved.

The analysis above illustrates a way in which a slowly brachiating siamang could maximise his net forward momentum from gravitational acceleration without exerting any propulsive force against the environment. In the same way that a child on a swing can increase the kinetic energy of that system by 'pumping', the siamang is able to maximise the kinetic energy of a single cycle by appropriately timed redistribution of its mass.

This work was supported in part by grants from the Hooton Fund, William F. Milton Fund and a biological training grant from the National Science Foundation to Harvard University, and the National Science Foundation to F. A. Jenkins, jun. All work in Malaysia was done in conjunction with the Institute for Medical Research, Kuala Lumpur and the Malaysia Game Department. I thank David Chivers for introducing me to the study of Malaysian primates. I thank R. T. Bakker, D. Fisher, R. Kay, J. Peterson and especially F. A. Jenkins, jun., for suggestions, comments and general encouragement and Laszlo Meszoly who prepared the illustrations.

book reviews

Metamorphic rocks

Metamorphism and Metamorphic Belts. By Akiho Miyashiro. Pp. 492. (Allen and Unwin: London, September 1973.) £8.60.

THIS book is a welcome addition to geological literature; it gives a clear and positive approach towards an understanding of metamorphism, metamorphic belts and associated phenomena, and summarises much of the relevant literature.

The book is divided into three parts, of which the first presents basic concepts and methods of metamorphism and metamorphic petrology, together with a chapter where some major problems of metamorphic geology are objectively discussed. The second and third parts respectively concentrate upon two major aspects of metamorphic studies: the detailed examination of minerals and mineral assemblages, important to an understanding of petrogenesis; and the broader study of the geological relations of metamorphic terrains of various types, whence the nature and conditions of major tectonic processes and crustal evolution may be elucidated.

Part 2 summarises much descriptive literature on numerous sequences of progressive metamorphism throughout the world, and discusses their interpretation with regard to the compositional and reaction relations of minerals and mineral assemblages. Attention here is particularly focused on the abundant data available for regionally metamorphosed pelites (actually referred to as metapelites!), metabasites, and metaclastics; but there are also chapters on meta-limestones and contact metamorphism, together with a lucid account of the relations of eclogites and the eclogite facies.

In part 3, Miyashiro describes the general nature and distribution of regional metamorphic belts in North America, Europe, Japan and the Southwest Pacific. This is followed by chapters summarising the main features of metamorphic belts and examining their place in the tectonic, geochemical, and major petrological evolution of the Earth's crust. There is a particularly valuable summary and discussion of metamorphism and island arcs in the Japanese Islands. Many features are discussed in relation to the recent concepts of seafloor spreading and plate

tectonics, and these are shown to allow much interpretation of the origin of paired metamorphic belts. Much clearly remains to be learned about other metamorphic belts. Chapters on ocean-floor metamorphism and cataclastic metamorphism are included at the end of part 3; the former is a welcome addition to the usual ambit of metamorphism, but the latter is very perfunctory.

The division of the book into the three parts outlined above is a useful and logical one, but has led to some repetition and the presentation of some subjects (such as facies and facies series) in two sections. Chapter 3, in part 1, is almost a summary of the whole book. An appendix on the "History of the Study of Metamorphism", helpfully puts different approaches and viewpoints in perspective; Miyashiro does not do justice to his own major contributions.

The facies classification is used principally as a basis for the major subdivision of the P-T field of metamorphism, and Miyashiro adopts Eskola's eight facies together with the recently widely recognised zeolite and prehnite-pumpellyite facies. He laudably avoids erecting further facies which cannot be clearly and positively defined by paragenetic relations and which are unlikely to be adopted by the non-specialist—the use of petrogenetic grids is indicated for detailed facies subdivision. At the same time Miyashiro distinguishes, somewhat anomalously, some subfacies on the basis of facies series, even though paragenetic criteria may not be available. By placing the emphasis upon individual progressive grade sequences, broadly separated into three basic types but without detailed subfacies division, the approach adopted contrasts with that of the recent books by Turner (McGraw Hill, 1968) and Winkler (Springer-Verlag, 1967) where divisions into facies and/or subfacies form major aspects or objectives of presentation. This feature, together with the extensive treatment of the broader geological relations of metamorphic terrains, will probably make Miyashiro's book the most appropriate and readable one for many undergraduate teaching courses.

Miyashiro notes that he has not intended any advanced treatment of thermodynamic and structural aspects. Summaries are presented for the ther-

modynamic characteristics of metamorphic reactions, the significance of isograds, and the nature of petrogenetic grids and Schreinemaker's bundles; but they are often too condensed to greatly help those who are not already aware of their import. Little attention is given to detailed petrography, or the relations of deformation and mineral growth. Miyashiro uses the old, rather vague, geological meaning of recrystallisation, instead of the more specific metallurgical one, recently employed by many metamorphic petrologists.

This book should prove useful not only to students and research workers studying metamorphism, but also to all those interested in the evolution of the Earth's crust.

B. HARTE

Desert plants drinking

A New Ecophysiological Approach to Forest-Water Relationships in Arid Climates. By I. Gindell. Pp. 142. (Junk: The Hague, 1973.) 40 guilders.

THE title of this book constitutes a claim to originality and that claim is amply justified within its pages. Gindell has taken a refreshingly novel look at the water relations of arid land plants. He has selected each of the anatomical and physiological properties which are normally associated with xerophytism, has systematically demolished entrenched assumptions and has constructed in their place a new and very personal philosophy of the xerophyte.

Some aspects of this reconstruction are more convincing than others. For example, he shows that many xerophytes have as many stomata on their upper leaf surfaces as they do on their lower surfaces; contrary to expectation, some xerophytes open their stomata during the night; following the exhaustion of available soil water, some xerophytes maintain turgour by the absorption of mist and dew, particularly during the night. Less convincing is Gindell's suggestion that water and even ions absorbed by stomata can be transferred to the soil through the roots, thus maintaining soil moisture levels beneath vegetation. He has not dealt adequately with the alternative explanation which relates the higher soil moisture beneath vegetation to the modified microclimatic conditions in such situations. Other, broader issues, such as overall transpiration rates in

xerophytes and even the function of transpiration in general are discussed, but no firm conclusions are reached.

The book is not easy to read. The language lacks fluent style, and, worse, many interesting thoughts are buried in a plethora of rather trite information. Often it is difficult to distinguish between the ideas for which Gindel has some experimental data and those which are purely speculative. The diagrams are embarrassingly crude and misspellings and misprints common.

In general, one is left with the impression that the book was prepared and produced in a hurry, which is sad because many of the ideas which are presented in it are stimulating and iconoclastic.

PETER D. MOORE

Life in space and time

Biogeography: An Ecological and Evolutionary Approach. By C. B. Cox, I. N. Healey and P. D. Moore. Pp. viii+179. (Blackwell Scientific: Oxford, 1973.) £3.00.

THIS is a very attractive book which is well illustrated and written in a lively and engaging style, so that it is likely to appeal to students at universities for whom it seems to be intended. But as with so many new textbooks, it tends to skim the cream and omit much of the milk from which the cream rises. It is fair to ask if such books are a proper diet on which to nurture a critical appreciation of an essentially descriptive and analytical subject, for this is surely what biogeography really is. It is the branch of science concerned with the study of distribution on a geographical scale of both fossil and living organisms and the communities and ecosystems of which they form a part. It cannot be conceived as including ecology and cytogenetics without destroying the meaning of words.

The authors have too broad a definition of their subject, at least when attempting to present it so summarily. With only 179 pages at their disposal, which includes numerous maps, drawings and photographs, the treatment is inevitably often superficial, even to the point of being misleading. A model of what is really needed for universities is provided by Stanley Cain's *Foundations of Plant Geography* (Harper, New York and London, 1944), an outstanding contribution to biogeography which is surprisingly not even mentioned in the references. In fact, the chapters on life on small islands and on continental drift approach this quality and present lucidly both the essential evidence and the arguments so that they serve to emphasise the weaknesses in other chapters. For example, the account of

soils is unbalanced. What is clearly a podzol, though this is not stated, is described on page 49 and gives an impression that most soils conform to this basic structure. The process of podzolisation is described subsequently. Surprisingly in a book of this title, there is no account of the great latitudinal belts of zonal soil types and no discussion either of the relationship between these and the major ecosystems of which they are a part, or of the conceptual parallelism between zonal soils and vegetational climax. Surely if a book must be so concise, it is these fundamental relationships and ideas which should be included and illustrated with a few carefully selected and adequately presented examples. Moreover, examples must be recognisable as such and not be mistaken for generalities. In fact, this technique is used in the chapter on small islands and its value is at once apparent.

There are a few confusing statements and discussions. On page 16, *Arbutus unedo* is correctly stated to grow "wild" in western Ireland, yet on page 17 its morphology and phenology are given as evidence that it is "not native". Could the same be said of *Hedera helix*? The discussion of interaction of factors and limiting factors on page 30 suggests a fundamental misunderstanding in the authors' minds. The text is almost free of trivial errors but the caption on Fig. 17 implies a knowledge of German which is scarcely appropriate for those who aspire to be the heirs of Alexander von Humboldt.

C. D. PIGOTT

Alpha rhythm from eyes

The Origin of the Alpha Rhythm. By O. Lippold. Pp. ix+267. (Churchill Livingstone: London and Edinburgh, 1973.) £6.

THE alpha rhythm of the electroencephalogram consists of electrical oscillations at about 10 Hz which can be recorded from the scalp, especially the occipital scalp, in most people during most of the time that their eyes are in darkness. Since the work of Adrian and Matthews in 1934 it has been almost universally believed that it is generated by the brain. Dr Lippold proposes the revolutionary idea that it is generated by muscular tremor in the orbits. The evidence comes chiefly from the following three observations. (1) A tremor of the eyes can be recorded which correlates fairly well with the alpha waves. (2) If the amplitude of the corneo-retinal potential is made different in the two eyes by dark-adapting one eye, the alpha waves from the occiput become larger on the side where the corneo-retinal potential is larger. (3) If one orbit is cooled and the other warmed (thereby presumably raising the

tremor frequency on the warmed side and lowering it on the cooled side), the alpha waves become of higher frequency on the warmed than on the cooled side.

If these observations are strictly and regularly true, I do not think that Dr Lippold's conclusion can be escaped. I therefore eagerly await their independent confirmation.

The implications of the conclusion for the conduction of current within the brain are remarkable. It is somewhat surprising that electrical waves generated in the orbit can appear much larger in records from the occipital than from the frontal scalp. It is much more surprising that they can be very large in direct bipolar recordings from the occipital cortex and undetectable in direct bipolar recordings from the precentral gyrus, only a few centimetres away and slightly nearer to the orbital fissures and optic foramen. Yet this, according to Jasper, is true of alpha waves.

G. S. BRINDLEY

Through the Earth

Physics of the Earth and Planets. By A. H. Cook. Pp. x + 316. (Macmillan: London and Basingstoke, September 1973.) £8.50.

THE author states that this book was written for second and third year undergraduate geophysics students and as background reading for graduate students. He defends the bias given to such topics as gravity, seismicity and certain dynamical behaviour of the planets on the grounds that present day students know more modern than classical physics. But the bias is rather narrower than this and the author seems to be only really sympathetic to those parts of earth science that make great play with displays of significant figures. How else is one to interpret the sentence (page 33) "The shape of the solid surface of the Earth is very irregular and of no general scientific interest"? Although there are chapters devoted to magnetism and crustal movement and some extremely sketchy descriptions of apparatus, my overall impression is of a book that could serve as an introduction to Sir Harold Jeffreys's *The Earth*.

There is a good introduction but later, in perhaps more important matters of detail than the consistent use of SI units, the standard of presentation becomes less meticulous than Sir Harold's. For example Laplace's equation is said to be "nothing more than a statement of the inverse square law" on page 27, whereas on page 28 that Laplacian fields are said to vary as r^{-1} . There follows a repetitious discussion of satellite motion and a treatment of geoidal shape, complicated

enough at the best of times, that is marred by sign errors. There are other indications of hasty preparation and inadequate proof reading. Why give a glossary of symbols when additional definitions (for example of m) are introduced into the text? Why give two diagrams of travel-time curves (pages 75 and 78) when one suffices and is there any need, even in a student text, to give diagrams of upper mantle velocity distributions (page 84) that conceal quite so many complexities of the observed situation?

There follow chapters dealing with oscillations and vibrations, the internal structure of the Earth (which ends with an entirely theoretical discussion of creep and the Q of materials), the radioactivity and ages of rocks and the temperature within the Earth. The latter chapter follows entirely conventional lines, based on thermal conduction theory although we are warned (page 171) that such calculations only apply to those parts of the Earth that are "rigid". Having been told in a previous chapter about the creep of rocks and that most of the mantle is at temperatures at which creep is "almost certainly important" (page 136), the student will wonder about the consistency of pursuing this particular line of enquiry. A quite erroneous description is given of phonon thermal conductivity (page 174), valence bands are described as localised electron states (page 175) and exciton energy transport is said to dominate other modes of the heat conduction process (page 176). A completely garbled account is given of the fundamentals of thermal convection theory, and the matter is not clarified by a quite incomprehensible fig. 7.11. I was very irritated by the implication that all is still confusion and ignorance in such an important problem of planetary physics, where definite progress has been made in the past ten years.

The remaining chapters deal with the permanent magnetisation of rocks, the geomagnetic field, movements of the Earth's crust and "The Earth among the Planets", the latter being largely concerned with the constraints placed on the density distributions in planets by classical astronomical observations and theoretical equations of state. Little reference is made to the new insights that have sprung from the space programme.

It is perhaps no criticism of a book intended for students that there are so few actual references to the work of living earth scientists, although a few names are dropped from time to time. Perusing the biographical notes at the end of the book, a student could be forgiven for believing that planetary science was the exclusive preserve of titled British scientists and finished with

the death of that well known geophysicist, Lord Rutherford. He will however find the questions at the end of most chapters a challenge to his understanding—even if they are a little contrived.

Since the publishers have performed their side of the production so satisfactorily, it is a pity that so much is unsatisfactory in its contents. I fully appreciate how difficult it is to be the expert in all branches of planetary science that such a title demands, but a little more care in preparation could have made this a much better book.

D. C. TOZER

Too brief a tale

A Revolution in the Earth Sciences: From Continental Drift to Plate Tectonics. By A. Hallam. Pp. vii+127. (Clarendon: Oxford; Oxford University: London, April 1973.) £4 boards; £1.75 paper.

THIS is a narrative historical account of the concept of continental drift. It is written in much too short a space to tell a story so deeply enmeshed in personality and full of drama. Dr Hallam deliberately aims to write "quite sparingly" and his book thereby takes on an encyclopaedic character. All the principal papers are described, though often in no more than abstract form, but the background is largely missing. He tells what was written, but not what was thought. Nor does he explain the extent of knowledge and ignorance at crucial times in the narrative.

Dr Hallam has painted a stark and static picture of the players. He has barely painted the scenery at all.

DAVID DAVIES

Substitutions

Aliphatic Nucleophilic Substitution. By S. R. Hartshorn. Pp. viii+172. (Cambridge University: London, November 1973.) £3.80; \$12.50.

THIS book is a useful member of the series of chemistry texts published by the Cambridge University Press and is certainly worth a place in any college or university library.

The author has given a clear account of nucleophilic substitution; the various methods of determining the type of reaction are discussed in detail and the problem of the "borderline" cases emphasised, an important feature since many undergraduates fail to appreciate this problem and believe that all substitution reactions fall into clear-cut categories. I was very pleased to see a section on the catalysed reactions, as the effects of silver and mercury salts on these reactions are often ignored.

In other places the treatment seems a little thin: for instance, eight pages of the book are devoted to secondary deuterium isotope effects and yet ambient nucleophiles only merit half a page and Kornblum's name does not appear in the list of references. Some space should have been used to discuss the important synthetically useful reactions and their limitations: dozens of graduates go out into the world each year believing that *t*-butyl bromide plus sodium malonate ester constitutes a useful synthetic reaction. In the index there is no reference to diethyl malonate or β -keto esters and the list of solvents does not include dimethyl sulphoxide.

A. S. BAILEY

Techniques for structure

Co-ordination Chemistry: Experimental Methods. By K. Burger. English translation edited by Ian T. Millar and D. W. Allen. Pp. 372. (Butterworth: London, 1973.) £10.

TITLES must be brief, so may be incomplete. This book describes experimental methods for providing structural information in coordination chemistry and does not cover measurements of equilibrium constants or the kinetics of complex formation. In a masterly introduction the author sets the perspective and in his final, the eleventh chapter, he shows with examples from glyoxime complexes how the various methods can be combined.

The intervening chapters each deal with specific techniques giving the principles, an outline of the methods and the type of information obtainable. The balance has been influenced partly by the length of time for which the technique has been available; Mössbauer spectroscopy has advanced so much since the Hungarian edition was published in 1967 that the chapter on it was rewritten and is now as long as that on IR and Raman spectroscopy despite their more general applicability. Post 1967 references are rare in the rest of the book, and the new technique, electron spectroscopy for chemical analysis (ESCA), provides most of these.

There is a particularly clear explanation of shielding effects in the chapter on nuclear magnetic resonance (by L. Brajer). In the first three sections on X-ray structure analysis (by Korecz) there is confusion between atoms and lattice points while the illustration of an electron density map, also on the dust jacket, is not of a coordination compound; Burger himself writes well on the results. An interesting account of thermal analysis (by G. Liptay) shows that this must be combined with other methods if structural information

is sought. The use of optical rotation and circular dichroism in stereochemistry are well described and the account of magnetic methods presents spin-orbit coupling with unusual clarity.

The book succeeds in its aim, to enable someone starting research to choose an appropriate technique for the problem. It is also readable and sufficiently clear to help someone struggling with obscurities in a more specialised text. The references and examples cover a wider range than the monolingual scientist usually meets, as shown by the author index which, with a subject index, is another good feature. The standard of printing and illustration is good; unfortunately few research students will be able to afford their own copies.

MARY R. TRUTER

Neurones connecting

Developmental Neurobiology of Arthropods. Edited by D. Young. Pp. vii+268. (Cambridge University: London, December 1973.) £5.60.

THE editor of these nine experimental and review contributions has wisely declined to erect principles or to look too hard for coherence within the phenomena covered by the volume. Such treatment might have exerted an intellectual 'closure' effect on a field involving many young as well as more experienced workers. Instead, the impression is preserved that contributors are usually defining questions which may in future be posed, using their experimental systems. The book is thus good reading for intending researchers and teachers, and not recommended for those in search of potted literature from which to bolster grand theory.

Readers with developmental interests, and vertebrate research experience, spend much of their time fascinated by features distinctive to arthropod as opposed to vertebrate systems, particularly the relatively small number of neurones, and the high proportion of these which seem to be uniquely specified and 'homologous' anatomically as between individuals. But they are continually reminded that the anatomical picture of a lower order of determinacy within vertebrate nervous systems does not itself rule out a comparable degree of cell specificity at some functional level. Thus arthropods may lend themselves well to developmental analysis while contributing greatly in future to knowledge of general principles underlying neural organisation, where such exist. Both aspects are stressed at points in the book. The concluding review by Horridge contains discussion of uniqueness among neurones, and the editor in his own contribution makes some very thought-provoking remarks (page 186)

on the homology concept as applied to cells within successive segmental ganglia.

Levi-Montalcini and her associates provide a rich source of technical information for initiates into insect nervous system tissue culture, together with evidence for specificity capacities of growing neurites that has so far emerged from such work.

Bate and Lawrence review the theory, concerning spatial organisation in insect development generally, with which the latter is associated, and then suggest its relevance to such organisation as studied in the eye-brain connections of vertebrates. They then show how a particular piece of specificity in sensory behaviour, emerging in an insect pupal stage, is explicable if different receptor cell-bodies form central connections according to their position in a quantitative antero-posterior gradient of positional information that controls epidermal pattern formation in general. In such a cross-disciplinary publication as this they might have discussed alternative theories available for positional information control, but the important point is made that if position within a cell array is signalled quantitatively only, then competitive mechanisms are strongly implicated in normal erection of neuronal projections. Edwards and Palka in fact offer evidence of synaptic competition during development, in their chapter on sensory regeneration.

The insect eye—optic lobe system, described by Meinertzhagen, deserves detailed acquaintanceship as perhaps the largest array of neurones known in which many are completely specified as to anatomical class and connectivity. Although making demanding reading, this chapter is perhaps the most exciting for the relative newcomer to arthropod neurobiology.

Pipa and Bentley each provide surveys of post-embryonic development, from functional and anatomical viewpoints, and Hoy introduces the rather outlandish properties of regeneration and survival in certain crustacean axons.

JONATHAN COOKE

Associates of viruses

Viruses and Invertebrates. Edited by A. J. Gibbs. Pp. xvi+673. (Frontiers of Zoology vol. 31.) (North-Holland: Amsterdam and London; American Elsevier: New York: 1973). Dfl 150; \$57.70.

THE editor of this book believes that it is vital to develop a unified approach to virology, to counteract a bigoted adherence to an order of events based on the taxonomic position of the host. This philosophy deserves active support. The topic of 'viruses associated with invertebrates' was a particularly good choice as it allows attention to be focussed on

both animals and plants. The enormous scope of the subject is however, demonstrated by the fact that the editor needed the assistance of thirty-three authors who contributed thirty-one chapters. It is understandable that, with so many collaborators, not only will variable standards of treatment and presentation arise but that dangers of superficiality and irrelevance may occur. But with one or two exceptions, Dr Gibbs has kept his troops under disciplined command and produced a valuable and stimulating book.

The names of the various sections owe more to the stage and art than to science and yet they stimulate interest in the contrasts and direction of thought contained within and between the various chapters. For example, to continue with the artistic analogy, "Tryptych" leaves an impression of a miniature dominated by two massive canvasses. The quality of the paper is poor: it is so thin that photographs on the reverse side of a page become obtrusive. Also, a general index of only two pages is derisory and one has to rely on the brief contents list of each chapter. The price of the book is high and it will probably only find its way into libraries, but it is worth borrowing.

Is space time?

Space and Time in the Microworld. By D. I. Blokhintsev. Pp. xiv+330. (Reidel: Dordrecht and Boston, Mass., 1973.) Dfl. 110; \$39.50.

BOTH relativity and quantum theory profoundly alter Newtonian concepts of space and time. Each theory introduces changes that are qualitatively different and their compatibility has been the topic of many debates. In special relativity, the individual process is still analysed in terms of point particles moving along trajectories in a manifold, although the interactions are always propagated with a bounded finite velocity. Quantum theory, on the other hand, only gives meaning to the individual process in terms of the ensemble and, furthermore, there seems to be an essential connectedness between interacting systems that are eventually spacially separated, giving rise to a correlation that seems to be non-local.

In the non-relativistic domain we know how to accommodate the quantum theory; the classical analogue of the phenomena can be successfully translated into the quantum algorithm, but once we move into the high energy region, the situation becomes somewhat confused. Does the essential connectedness of quantum theory imply that space-time descriptions are futile and that Lorentz invariance should be introduced through energy-momentum considerations alone or should we ask questions about possible modifications to space-time geometry? Indeed, the aim of Professor Blokhintsev's book is to present a critical analysis of this type of question.

He begins by developing the mathematical description starting from the Minkowski formalism of space-time, passing briefly through field theory, finally arriving at the S-matrix formalism which is to form the basis for the rest of the investigation. In fact, he goes as far as to claim that the S-matrix will be retained in all future theories, although the methods of constructing the matrix elements may undergo radical changes.

His main thesis then centres around the question of causality. In particular, he considers the consequences of replacing microscopic causality by a less restrictive form of macroscopic causality. This allows some form of acausality, or non-locality, in small space-time regions, while retaining causality in the large. The S-matrices constructed using either principle of causality differ only at energies that are much greater than the reciprocal of a fundamental length. Experiments show this to be less than 10^{-14} cm and the author speculates that it could be 10^{-16} cm, the characteristic

weak-interaction length. But the arguments are slender and it could equally well be at 10^{-33} cm, the gravitational length, in which case further investigation might be discouraged. It has, however, often been suggested that the infinities in both classical and quantum field theories could be removed by changing the geometry in the small and the advantage of the principle of macroscopic causality is that it allows an exploration of various possibilities without leading to large-scale acausality. The final chapters are concerned with this question and discuss, in particular, the effects of discrete space-times, stochastic space-times and fluctuating geometries.

These final chapters left me feeling a little disappointed that more space had not been given to the question of generalised geometries. I find this a very fascinating field in which many questions are still unanswered. Indeed there is quite an extensive literature on the subject some of which is quite closely related to the topics discussed in the book but unfortunately no reference is made to this work. Apart from this small reservation, I find the book very clearly written, and even the liberal use of mathematics has not been allowed to obscure the essential questions.

B. J. HILEY

All sorts of skin

The Integument. A Textbook of Skin Biology. By R. I. C. Spearman. Pp. vi+208. (Biological Structure and Function, vol. 3.) (Cambridge University: London, June 1973.) £4.20; \$12.95.

BECAUSE of the explosive developments taking place in science in general and biology in particular and because of the trend toward more and more specialisation, books which give a broad, comprehensive view of the subjects included under these headings have become a rarity. Thus, I began to read this book with some anticipation which was further whetted by the author's commitment to provide a bird's-eye view of the whole subject of skin biology. As the author states in his preface, the comparative approach to the study of the outer covering of both invertebrates and vertebrates has not been attempted before; hence any book purporting to do so should be expected to fill a long-felt need. Unfortunately, *The Integument* fails to live up to these expectations and does little more than catalogue the various aspects of skin biology under various headings.

The book is divided into two parts, the first of which treats the comparative morphology of the integument of both invertebrates and vertebrates. Here

Spearman deals with the epidermal, dermal and pigmentary aspects of the integument of various phyla of invertebrates and of five classes of vertebrates (Pisces, Amphibia, Reptilia, Aves and Mammalia). This section is nicely illustrated with numerous line drawings which should help the beginner to understand the structural details of many of the skin appendages.

In the second part, the book deals with the comparative functions of skin, such as thermal regulation, chemical and neural control mechanisms, comparative synthetic processes, transport through the skin, immunity and development. The titles are provocative, but the cursory treatment leaves much to be desired. For example, in the chapter on the comparative synthetic process, only ten pages are devoted to such varied topics as genetic code, protein syntheses, elastin, resilin, collagen, and a host of others.

Brevity may be the soul of wit, but since wit is hardly the reason for undertaking a study such as this, the kind of one-sentence treatment accorded to important topics by Spearman while serving to whet the appetite does little to allay the hunger for substantial data.

PAUL PARAKKAL

Kidney disease

Renal Histopathology: A Light Microscopy Study of Renal Disease. By Robert Meadows. Pp. xii+363. (Oxford University: London and New York, December 1973.) £14.

WITHIN the limits of the title Dr Meadows has written an interesting and very well illustrated book. It will be useful to all pathologists who examine renal biopsies and to the many physicians who seek to understand the structural changes in their patients. While agreeing with the author that most diagnoses can be achieved with the light microscope, fortified by knowledge obtained by others with ultrastructural and immunofluorescent methods I feel it is a pity that there is not more reference to these in the text and some illustrations of the immunofluorescent results which after all are obtained with the light microscope.

The consideration of glomerular changes and glomerulonephritis is comprehensive and clear although the separation of the two leads to a certain amount of recapitulation. The section on the disappearance of glomeruli from the kidney is welcome in that it considers a difficult point which most authors skate over. Dr Meadows is not alone in attributing the clear description of what he calls the ischaemic obsolescent glomerulus to McManus (1950); it was in fact recognised by Russell (1929) by the

less cumbersome term of ischaemic atrophy. She used the term toxic atrophy for a glomerular lesion in chronic glomerulonephritis which is redescribed in more detail by Dr Meadows who puts forward the thesis that some cases of chronic glomerulonephritis develop as a progressive form of focal disease. In her Medical Research Council Special Report (No. 142), Russell (1929) had an interesting name for this concept—nephritis repens—which has never caught on. Perhaps these reports repose in dusty basements or galleries of libraries in Australia just as they do in this country.

The chapters on tubular disease are not quite as good as those on glomerular because of a lack of adequate integration with experimental work. In understanding the changes in biopsy and necrosis material from acute tubular necrosis, for example, it is essential to appreciate the appearances of regenerating tubular epithelium at various stages—the details of which are most easily seen in experimental mercury poisoning. The only consideration of such regeneration is confined to ischaemic tubular necrosis and the sequence is not brought out. The part which obstruction may play in the pathogenesis of tubular damage is not discussed; in this respect it is unfortunate that the paper of Bywaters (1946) in which he brought out the resemblance between changes in acute hydronephrosis and the crush syndrome has never received proper recognition.

J. F. SMITH

Pictures of viruses

Ultrastructure of Animal Viruses and Bacteriophages. An Atlas. Edited by A. J. Dalton and F. Hagenau. (Ultrastructure in Biological Systems vol. 5.) Pp. xii+413. (Academic (Harcourt Brace Jovanovich): New York and London, September 1973.) \$37.50.

THIS book contains a splendid collection of electron micrographs illustrating the structure and development of 65 animal viruses and bacteriophages. Though the text is variable from chapter to chapter it is mostly concisely informative. The index is very comprehensive but it did not include the Sendai virus, which is now much used in cell fusion studies.

The chapters are divided according to the virus groupings laid down by the International Committee on Nomenclature of Viruses (ICNV). Each begins with a concise account of the structure of the virion and of its intracellular replication. As might be expected the text is not a comprehensive treatise on each group of viruses nor is each group uniformly treated. For instance R. W. Horne and B. Roizman each devote nine pages to their respective groups the adenoviruses and the herpesviruses,

whereas N. Higashi and A. J. Dalton fill only one page each about the togaviruses and the arenaviruses. Nevertheless all the chapters have useful lists of references.

Several authors have been particularly helpful by giving clear accounts of more obscure aspects of their chosen group. A. J. Dalton and F. Hagenau define the A, B and C particles found in neoplastic tissues and G. C. Goodman gives a detailed account of the cytopathic events in cells infected with picornavirus in the captions to the illustrations. J. L. Melnick gives an account of the efforts of the ICNV to name and classify the viruses.

It is a pity that a book which treats the animal viruses so fully should expend two chapters on bacteriophage but exclude the viruses of plants and invertebrates. But the book completely achieves its editors' aims, provides a valuable work of reference for the animal viruses and gives a concise view of the bacteriophages.

D. KAY

Cosmic rays reach earth

Cosmic Rays at Ground Level. Edited by A. W. Wolfendale. Pp. vii+232. (Institute of Physics: London and Bristol, 1973.) £12.00.

As a tribute to Professor G. D. Rochester on the occasion of his retirement, nine authors associated with the cosmic ray group at the University of Durham have chosen to write ten short reviews, in which they have summarised the present situation in experimental work on the fluxes of the various components of the secondary cosmic radiation detected at "ground level", in chapters on energetic muons (M. G. Thompson), protons and pions (Brooke), neutrons (Ashton), μ -neutrinos (Osborne), e -neutrinos (E. C. M. Young), extensive air showers below 10^{17} eV (Wdowczyk) and above 10^{17} eV (Turver), and on searches for quarks and other hypothetical particles (Ashton). The work is not about the primary cosmic radiation, although for completeness a preliminary chapter (Wolfendale) sketches in some of its aspects. There is added a comprehensive account of the technique of observing trajectories of fast charged particles by neon flash tubes (Breare), a method used by most of the authors.

In several chapters the aim is principally to collect data on the particle fluxes near sea level, and the "ground" in the terms of reference strictly excludes mention of experiments at mountain altitudes: hence a theoretical framework for interpreting the observations is not the aspect of interest. In the circumstances it is natural that the authors, apart from collecting published data, present progress reports which tend to lean heavily

for illustration on the experiments in which they and their colleagues took part, in the research groups founded by Rochester and Wolfendale; although extensive references are given to other experiments.

In the most substantial review, on observations of momentum spectra, angular distributions and charge ratios of energetic muons, readers with a peripheral interest in the subject may be surprised by the extent to which for many years results have depended on normalisation to an old experiment by Greisen: only recently has the normalisation been revised (by Allkofer and others), and it is useful to have this documented. (It is a pity though that the "ground level" rule bars any reference to the work of the Utah group.) Although some problems currently raised by the interpretation of the charge ratio are briefly introduced, the significance of the vertical momentum spectrum is not discussed. The reviewers of hadrons have very little to work with at energies above a few GeV, mountain experiments having been more numerous, and the distinction between pions and protons (at sea level) evidently remains a problem. Here, though, a discussion of the method of deducing the energies of hadrons in the TeV range from the cascades they produce would have been welcome, as different experiments are almost certainly not using the same scale. (In the short chapter on neutrons, the method used to measure their spectrum is not mentioned at all.) And for all very high energy spectra, one would have liked to know how much accompanying particles might affect the measurements.

To observe neutrinos one has to go to deep mines, but with the excuse that the fluxes there and at sea level must be the same, Osborne gives a clear account of the three main experiments on μ -neutrinos, and their significance. Young and Ashton have no positive observations to report on their exotic particles, but they indicate what intensities might reasonably be sought. In the articles on extensive air showers the emphasis shifts to illustrating progress being made by the authors and their colleagues in constructing models of shower development, which is a necessary preliminary to firm deductions about the energies and nature of the primary particles; although Turver also presents recent estimates of the energy spectrum, and isotropy, and recent work on the distribution of several particle components of air showers, largely from the Haverah Park experiments.

The fluxes of electrons, gamma rays and slow neutrons are not reviewed. It is a pity that the price is so high for a welcome but relatively short book.

A. M. HILLAS

matters arising

T-mycoplasmas and infertility

SIR,—IN the first report about the association of T-mycoplasmas with human infertility the authors considered that the high incidence of isolation (89%) from the cervix of infertile women compared with the low incidence of isolation (23%) from pregnant women suggested that the T-mycoplasmas were playing some rôle in the infertility. This was based on the isolation discrepancy and was principally a result of the low incidence in pregnant women. Others have, however, been more successful in isolating T-mycoplasmas from pregnant women. Mårdh and Weström² isolated T-mycoplasmas more frequently from pregnant (68%), than from non-pregnant women (46%), and thought that the former rate might have been due to changes in the genital tract at pregnancy conducive to the growth of T-mycoplasmas. Gnarpe and Friberg tried to substantiate the possible association of T-mycoplasmas with infertility by treating infertile couples with tetracycline and 29% of the women they treated subsequently became pregnant. In the absence of untreated controls, however, this finding is meaningless. Mr G. T. Smedley and I, in an unpublished study, found that of 32 infertile women, 22 (69%) carried T-mycoplasmas. Within a year, nine of these women became pregnant without treatment and 5 (56%) of them carried T-mycoplasmas. Gnarpe and Friberg's second report³ concerns the attachment of T-mycoplasmas to human spermatozoa. I find it difficult to regard the 'blobs' on the spermatozoa that they saw by electron microscopy as evidence for attached T-mycoplasmas, as these structures could also be *Mycoplasma hominis*, chlamydiae or some other agent. I do agree, however, that adherence of human T-mycoplasmas occurs in the same way as those of bovine origin adhere to bovine spermatozoa⁴. It is interesting that practically all bovine semen samples that we examined contained T-mycoplasmas, yet they all had a high fertilising capacity⁵. It seems likely that abnormal appearance, low motility and viability of spermatozoa in man are not due to the presence of T-mycoplasmas in semen, because the organisms are isolated from such samples no more frequently than from samples which contain apparently normal spermatozoa. Spermatozoa of low fertilising potential might also be

adversely affected by mycoplasmas present in the vagina and cervix. This comes back to the original point about the incidence of T-mycoplasma isolation from these sites. Whether the incidence of isolation is greater in infertile women is a moot point, but it would also be interesting to know whether they harbour more organisms in the genital tract than do fertile women. I feel that the evidence put forward to incriminate T-mycoplasmas as a cause of infertility is far from convincing and that they are being placed on a pedestal that they do not, so far, deserve.

Yours faithfully,
D. TAYLOR-ROBINSON

⁵ Taylor-Robinson, D., Thomas, M., and Dawson, P. L. *J. Med. Microbiol.*, **2**, 527 (1969).

DRS GNARPE AND FRIBERG REPLY: we have read with interest the above letter and although Dr Taylor-Robinson's comments are valuable we have by no means expressed the opinion that T-mycoplasmas might be one of the major causes of infertility.

There are, however, a few points we wish to make clear. In our first investigation¹ we found a high incidence of T-mycoplasmas in infertile men and women compared with a lower incidence in men and women with proven fertility. All infertile patients had an unexplained infertility of 15 yr or more. None of the spermatozoa specimens investigated had abnormal appearance under light microscopy, low motility or reduced viability. We still consider that the incidence of pregnancy after tetracycline treatment is higher than can be expected to appear by chance among patients with this long-standing infertility².

We agree with Dr Taylor-Robinson that the 'blobs' on human spermatozoa discovered in scanning electron microscopy might be other agents such as *M. hominis* or Chlamydiae. In all specimens where cultures were made of

thoroughly washed spermatozoa³, however, we found T-mycoplasma colonies and not other agents growing. Whether Chlamydiae were present or not was, of course, impossible to establish with the technique used. We also found that some T-mycoplasma isolates produced substances cross-reacting with neuraminidase antibodies and suggested that these substances might render conception more difficult³.

These findings make it possible that some T-mycoplasmas might be of importance for some cases of unexplained infertility.

African swells, magmatism and plate tectonics

SIR,—Some of the 'flaws'¹ in my lateral compression model² seem to be matters of faith, for example, that the model is "at odds with modern global tectonics", whilst many (including the "petrological observations") are arguable matters of interpretation. One "flaw", apparently supported by data, concerns the faster rate of uplift of post-glacial regions compared with the doming of East Africa. It is argued that since there is no evidence of deep partial melting in the post-glacial regions, the probability of such melting by warping of the African craton is insignificant. But the two mechanisms are quite different. The post-glacial regions are rising in response to a uniform isostatic pressure at the base of the plate. Below the post-glacial uplift there is no localised decompression, as might be the case below an 'upwarp'. As was pointed out in 1964 (ref. 2), in the case of the African swells "lighter material would have to be added at depth to compensate each succeeding uplift". So far as I am aware, this deduction has not been challenged, nor an alternative offered.

In any case, since 1964 my original hypothesis² has been considerably modified and refined³, and Gill's critique is

therefore something of an anachronism. In particular, the interested reader will find³ the evidence and arguments against the idea (said by Gill to be "widely regarded") that the "topography of Africa is . . . the product of heat flow anomalies in the upper mantle". An alternative is proposed which is more in keeping with the facts.

Science and public pleasure

IN a recent interview on BBC television, Dr J. Bronowski was talking about job satisfaction. "Scientists and prostitutes", he said, "have one thing in common—they both get paid for doing something they enjoy." Many would question the enjoyment that Bronowski attributes to prostitutes but surely scientists enjoy themselves.

We looked, a few months ago, at the fun side of enjoyment—the scientific jokes of various guises—and this need not detain us here. What we now consider is the more lasting aspect of enjoyment; job satisfaction, but more than that. Some jobs offer satisfaction to the doers but hardly to others, certainly not to the general public. One does not, for instance, expect a stockbroker, however personally satisfied by his job, to look for any sort of public acclaim. At the other end of the spectrum are those who offer some sort of pleasure to the general public, not necessarily to their own satisfaction (for example, prostitutes, troubled poets and so on). Where do scientists, and in particular research scientists, fit into this scheme? There is clearly not a preordained slot in a satisfaction diagram for scientists but the question is valid, partly because recruitment into science depends substantially on how much practitioners are perceived to enjoy themselves and partly because the question of a more public delight in one's work is something about which scientists are ambiguous.

There are, doubtless, many surveys carried out among scientists of how happy they are with their job. Such surveys are of little use if they comprise no more than a question, 'Are you happy in your work?' Few will admit to being unhappy; not only is it an admission in itself but it also reveals the vulnerability of the highly trained person who has few options to move other than within his specialisation. The question 'do you give other people pleasure through your work?' is a more difficult and telling question. It is also one which will be dismissed by many as irrelevant. 'Science is not show business.' But it is, and there is nothing disreputable about show business, which comprises music as well as music hall, theatre as well as circus.

Many myths about scientists have been exploded in the past ten years and among these has been that the scientist has some sort of detachment both with regard to his personality and to his way of doing things. *The Double Helix* must surely have been the most eloquent source of this demythologising. And yet the emotions which Watson so vividly and honestly portrays are not confined to those who make the greatest of discoveries; in a sense they are even stronger among those whose names have not become household words because the final accolade is still to come (or never will). It is inconceivable that a vast majority of research scientists

do not live with thoughts and hopes of wide recognition and acclaim, and positively revel in such exposure as comes their way. Which is what show business is about.

The acclaim is, of course, somewhat rarefied by the standards of the world. Some may be perfectly happy with the occasional paper in a learned journal, but they are a minority. A paper in *Nature*, a review article in *Scientific American*, these are more attractive as an opportunity to display one's skills to a wider public, even though the wider the public the less discriminating they can be. And the ultimate for most is publicity before a universal and thoroughly (indiscriminating audience) through the mass media.

It is at this level that most scientists become studies in ambiguity. Pleasing as it is to see oneself in print or on television is it not a trifle vulgar, and should the media not be kept at a discreet distance? Surely not. The general public can certainly take a delight in things it does not understand. There are many levels on which one can enjoy a performance of *Hamlet* and there are similarly many levels at which a scientific accomplishment can be savoured. Further, the scientist who refuses to have anything to do with the media is letting in the professional commentator, already at one remove from the field. Misrepresentation is then not the commentator's fault but the scientist's.

Ability to reach a more general public is not at present uniformly spread over the sciences. Although some fields seem to command wide and appreciative audiences, others never seem to project themselves. Chemistry is a case in point. Many chemists entertain serious doubts that their subject can be of interest (other than financial) beyond their own community. This may be true, but it is worth regular efforts to find out whether chemistry has an appeal.

100 years ago

A REUTER's telegram from Aden, of March 23, states that the steamer *Calcutta* arrived there from Zanzibar on the previous day with the body of the late Dr. Livingstone. We fear this must be regarded as final, and as shutting out any further hope; we can only now do all possible honour to those remains which the doctor's faithful servants have so religiously preserved. A letter recently received from Zanzibar, by Mr. R. A. Laing, states that the body, after having been exposed to the sun for a month to dry, and then packed in a hollowed tree, was wrapped round with cloth, and the natives carrying it supposed it a bale of cloth, or kaniki.

From *Nature*, 9, 410, March 26, 1874.

Centre for the practice of theory

Next September, the International Centre for Theoretical Physics in Trieste will celebrate its tenth anniversary. In a decade it has become a major, but still unique, feature of the scientific world. Professor John Ziman, of the University of Bristol, describes its problems and successes.

THE International Centre for Theoretical Physics (ICTP) was inspired by Abdus Salam, professor of theoretical physics at Imperial College, London, who recognised, from personal experience, the need for a place where young and promising research workers from developing countries might come from time to time to "recharge their intellectual batteries". Salam persuaded the International Atomic Energy Agency (IAEA) to create such a centre, which came to Trieste at the invitation of the Italian government and of the City of Trieste.

After some years in temporary premises in the centre of the city, the ICTP moved in 1968 to an elegant building paid for by the regional government and the city. This building overlooks the Adriatic, about 8 km north of Trieste along the main coast road, and has offices and lecture rooms for about 100 physicists at a time. In the summer, naturally enough, the place is crowded, but the building is now in fairly constant use throughout the year. Unfortunately, domestic accommodation has to be found in hotels or lodgings in the city, which means a lot of bus travel; there are long term plans to provide a hostel nearby. The centre has its own excellent library, but the nearest computer facilities are in the University of Trieste. The material facilities are better designed for high-minded individual cerebration than for team research on dirty facts.

Noble laureates and brash young physicists

About 5,000 physicists from 90 different countries have visited the ICTP since it was founded. Of these, at least 1,000 have worked there for periods of several months or more. Visitors range from academicians and Nobel laureates, on courtesy calls of a few days or weeks, to brash young theoretical physicists from developing countries on nine-month fellowships or associateships. But the centre is not an 'institute' with a permanent academic staff committed to a long term research and teaching programme. By arrangement with Imperial College, Professor Salam, the director, spends two-thirds of his time at Trieste, and Paolo Budini, the deputy director, is also a professor at the University of Trieste. Other Trieste professors work regularly at the centre, but do not dominate its activities. In principle the scientific programme of the ICTP is guided by a Scientific Council, nominated by the various sponsoring agencies, which meets for a couple of days annually; in practice, the initiative rests almost entirely with Salam and Budini, in cooperation with various senior scientists who have become involved in the programme of the centre over the years.

A small, hard working technical staff provides administrative, secretarial, library and printing services.

The precise constitution of the ICTP as an international organisation is not easy to explain. Legally it is a part of the IAEA and UNESCO, although the administration is mainly done by the IAEA. Financial support is shared in about equal proportions by the IAEA, UNESCO and the Italian government. Some matters have to be referred to the headquarters of the IAEA at Vienna and to UNESCO in Paris: others are dealt with by a 'consortium' of local Italian academics and officials. Funds for major activities at the centre also come from the United Nations Development Programme (UNDP), the Swedish International Development Agency (SIDA) and, until recently, from the Ford Foundation. Various overt or hidden subsidies come from such bodies as national scientific agencies. An income of about \$1 million a year looks healthy but policy changes, earmarking, exchange fluctuations and other sources of variance or constraint make each year's budget a work of art. The best that can be said of this confused situation is that the centre itself is not burdened with detailed external controls or a heavy bureaucracy, and has been free to find an ecological niche for itself in the jungle of international organisations—who themselves have shown wisdom and restraint in not crushing this strange little beast underfoot.

Changes from experience

Originally, the main purpose of the centre was to provide shelter and intellectual companionship for a number of 'associates'—theoretical physicists of proven competence, taking temporary leave from their academic or government jobs in developing countries for a few months each year to undertake advanced research and to refresh their minds by contact with their peers. This research was to be directed and inspired by distinguished visiting scientists from more advanced nations, for example American professors on sabbatical leave. Naturally enough, opportunities for advanced seminars, small conferences and short study courses would also be exploited as the occasion arose.

It must be admitted that this initial plan has been overshadowed and modified with experience. The quality of the research produced by associates at the centre was very uneven and their need for very close personal supervision could not always be met, simply because there were not enough senior people who could come to Trieste for long periods without financial support. Many of those chosen as associates were ill prepared for self-winding research in an atmosphere of scholarly independence. This defect is difficult to avoid when candidates must be selected on the basis of written applications from a distance and is particularly serious with applicants from small countries with very weak scientific traditions. In some fields of physics, therefore, the associate scheme is now being used mainly to help research workers whose ability has been confirmed by the part they have already taken in other ICTP activities.

Contribution

The research output of the centre (about 100 papers a year, of which half are by physicists from developing countries) is, in fact, quite substantial. In certain specialised fields of elementary particle theory, such as group theoretical methods, the use of non-compact groups and the connections with the theory of gravitation, it is the leading place in the world. In other fields the preprints circulated from the centre often represent important preliminary stages in investigations that are continued and completed elsewhere.

But the contribution of the ICTP to physics should not

be judged from the research actually done there. In recent years, much more emphasis has been given to 'extended seminars', 'winter colleges' and so on, where whole fields of advanced physics are systematically expounded by invited lecturers of the highest international reputation. For each such course, scholarships are given for 30-50 participants from developing countries to come to Trieste for 2-3 months. These courses are open, without fee, to appropriately qualified scientists from all countries and are well patronised by physicists from West Europe. Trieste is geographically well placed to receive physicists from East European countries, whose participation in the ICTP would be even greater if it were not severely limited by exchange controls and other administrative restrictions on travel. The Soviet contribution to the scientific programme has not been as great as was originally hoped but there have been long periods of collaboration at the centre between teams of plasma physicists from the Soviet Union and the United States.

A group of physicists at the ICTP, Trieste.

Many of the best physicists in the world, senior and junior, may be found talking together in the seminars, 'congressini', and 'research workshops' that arise spontaneously during or after each extended course. The centre has thus become a major forum, or market place for the international physics community. Personal contacts are established, ideas are exchanged and new developments communicated in a more leisurely and relaxed environment than the conventional scientific conference or summer school. The general atmosphere is serious and business-like; discussion ranges from the technical problems of mathematical physics to the role of the scientist in a developing country. The typical participant is about 30, has his PhD and several published papers to his credit, and is already carrying responsibility as a university teacher or in a newly formed research group in his own country. But the name on the office door speaks of Nigeria or Brazil, of Pakistan or Korea, rather than the United States, Europe, the Soviet Union or Japan. This is one of the few international scientific institutions in the world that is not dominated by people from economically advanced nations—and that is not just a political talking shop.

In founding the centre, Salam naturally concentrated on his own field of research, the theory of elementary particles. This remains a major component in a scientific programme which now includes regular activities on the physics of nuclei, atoms, molecules, plasmas, condensed matter, living organisms and the Universe, and on mathematical topics

such as computational methods, global analysis, and fluid dynamics.

Highbrow theoretical meetings such as an International Symposium on Contemporary Physics are balanced by courses that get down to hard experimental facts, such as the 1974 Winter College on 'Surface Science'. The centre now caters for the experimental physicist who wants a simple explanation of the theoretical background of his research as well as for the 'theoretician' with his abstract mathematical models. The proportions of the mix are mainly determined by the relative enthusiasms of various individuals who are willing to organise various activities, but would not perhaps be very different if there were a long term plan, based on firm financial guarantees, thought out carefully by a representative committee.

The facilities and programme of the ICTP are now much valued by the world physics community. It is well known as a good place to work at for short periods and the high standard of the extended seminars is coming to be appreciated both by potential lecturers and by their audience. But it still suffers from a shortage of active personal support and practical commitment over long periods from those leading physicists who could help so much in the scientific direction of its activities. Labour is an essential component of the fine ideal of international scientific collaboration.

Serving interests

Does this programme serve the genuine interests of the developing countries? The argument that the real need is for engineers, doctors, technicians and other practical experts is valid on the whole, but ignores the contribution that quite small numbers of well informed and competent academic research workers can make to the solution of technical problems, to educational standards and to cultural life.

Over the years, the activities of the centre have slowly shifted towards the more applicable branches of physics, in response to the political demand for greater 'relevance' to social needs. Indeed, this shift has not been altogether passive: physicists from developing countries meeting together in Trieste as a distinctive group begin to realise for themselves that the pursuit of pure science should not be regarded as an end to itself. In the extended seminar programmes, the intellectual continuity is emphasised between, say, the theory of elementary excitations in covalent solids and the technology of semiconductor devices. This provides a bridge over which the young scientist may move from the academicism of the old-fashioned physics curriculum to the more practical territories of engineering and industry.

A natural extension of the programme of the centre is to support similar activities in other regions of the world. This can only be done on a very limited scale, without permanent facilities, but should eventually strengthen the social and intellectual links established between physicists of various countries when they meet at Trieste. The ICTP cannot, of course, replace the great centres of physics research that exist in advanced countries and that are growing up in many developing countries, and can only supplement the specialist conferences, travel scholarships, regional summer schools and so on that already bind together the world scientific community. But because it is a place where the scientist from a developing country feels he comes as of right, and where people work hard together, on an equal footing, to the highest intellectual standards, it makes a unique contribution to international cooperation and national development. It thus represents a sound prototype for similar institutions in other fields of science and scholarship.

international news

The milk of human unkindness

John Hall

WAR on Want, a British agency pledged to make an urgent political issue of poverty, has accused western manufacturers of causing disease and malnutrition by promoting sales of powdered milks in Third World countries where their use is both unnecessary and unsuitable. In a report called 'The Baby Killer' War on Want says that babies in developing countries are dying because of bottle feeding, and many that do not die are drawn into "a vicious cycle of malnutrition and disease that will leave them physically and intellectually stunted for life".

The basis of the accusation is that sophisticated western marketing methods are being used to persuade mothers in Africa, Asia and Latin America to abandon breast feeding in favour of artificial substitutes. While these substitutes might make perfectly adequate infant foods under proper hygienic conditions, and play an important role in disaster situations when there is no alternative, they become dangerous when used continuously by mothers incapable of reading instructions and in kitchens where there is no clean water for mixing and sterilising.

According to the report the baby food industry stands accused of promoting its products in countries which can't use them properly, and of using advertising and supplying samples and free gift gimmicks that persuade mothers to give up breast feeding, often with fatal results for their children. The mothers often receive the impression that information they receive from commercially based advisers is something in the nature of nutrition education, and 'The Baby Killer' singles out as particularly unethical the use of medically unqualified sales girls, dressed in nurses' uniforms and offering a sales pitch dressed up to look like objective feeding advice.

Other practices which the report describes as unethical and immoral include the encouragement given to mothers to bottle feed while they are still breast feeding satisfactorily, and before there is any need for supplements and the payment of qualified nurses on a sales-related basis belying their educational

role. According to a source within the industry, these nurses are not only paid a commission on sales, but are given an additional incentive in the form of a promise that they will be fired if they don't meet their targets.

The problem of bottle-carried infection is well known in the Third World, if not widely publicised in the west. Even in Britain, where standards of living are comparably high, and most families live in hygienic conditions, hospital statistics show that babies still suffer from infections passed on from feeding bottles. War on Want points out that in the slums of Latin America and the squatter suburbs of Africa, where comparable conditions are hopelessly beyond reach, the choice of an artificial substitute for breast milk is in reality a choice between health and disease—disease caused by an infection or by long term malnutrition.

Breast milk cannot be improved upon as far as infant feeding in underdeveloped countries is concerned: it comes ready mixed, needs no warming or sterilising, leaves no dirty pots and bottles to be washed, and is almost always on tap from its carefully evolved, unbreakable containers. What's more, it contains an appropriate mix of proteins and fats, and seems to offer young infants protection against disease. In Chile, where 20 years ago 95% of one-year-olds were breast fed, the figure is now down to 20% at two months old: at the same time researchers have found that Chilean babies who were bottle fed during the

first three months of their life suffered a mortality rate treble that of breast fed infants.

The Protein Advisory Group of the United Nations (PAG) has produced a table expressing as a percentage of the national minimum wage the cost of artificially feeding a baby. It shows that in Nigeria the cost of feeding a three-month-old infant is about 30% of the minimum urban wage, and by the time the child is six months old the cost will have risen to a crippling 47%. In Pakistan, comparable figures are 40% of the wage at three months, 62% at six months. Not surprisingly, mothers attempting to bottle feed their children at this rate of exchange try to eke out their supplies by overdilution, so that the children to whom the over-watered milk is fed receive an inadequate intake of nourishment. They are left weak, vulnerable to infection, and often end their lives falling prey to wasting diseases like kwashiorkor.

The PAG manual on feeding infants and young children recognises the problem when dealing with powdered milk supplies. "In the less technically developed areas of the world", it says, "immediate and serious basic difficulties attend attempts to artificially feed young infants on a cows' milk formula. These include lack of sufficient money to buy adequate quantities, poor home hygiene (including water supply, fuel, feeding utensils, storage etc) and inadequate nutritional knowledge of the mother. Under these conditions, usual for the

majority in less developed countries, artificial feeds mean the use of too diluted, highly contaminated solutions of cows' milk, resulting at the best in undernutrition, at worst in marasmus and diarrhoeal disease".

And Dr James Farquhar, a reader at the University of Edinburgh and consultant paediatrician at the Royal Infirmary of Edinburgh, reinforces the point in terms which virtually precis War on Want's message: "It is clear to all but those who will not see", says Dr Farquhar, "that informed, adequate and relatively safe bottle feeding must follow, or at least accompany but never precede, literacy, education, infection-free water supplies, sanitation and a standard of living which permits the purchase of enough baby foods, equipment and the means of sterilisation".

The priorities for dealing with the trend away from breast feeding, described by the report as a trend which can only have calamitous consequences, have been stated by the PAG in the following terms:

"The major overall need is to alert governments, health services, nutritionists and the food industry to the emergency situation likely to develop in urban areas in the near future. Its implications are not only the certainty of rising mortalities from almost epidemic marasmus and diarrhoea but also the economic burden of curative services and of obtaining breast milk substitutes on a large scale as well as the long term consequences of the effects of recovered cases of infantile malnutrition on the intellectual level of the community".

War on Want says the aim of its 'Baby Killer' report is to achieve a solution to the problem by opening up the subject to public debate, and it makes recommendations both to the industries and the governments involved. The companies producing dried milk should follow the Swedish example, they say, and refrain from all consumer promotion of breast milk substitutes in high risk communities. They should cooperate constructively with the international organisations working on the problems of infant and child nutrition in the developing countries, and they should abandon promotions to the medical profession which may perform the miseducational function of suggesting that particular brands of milk can overcome the problems of misuse.

Governments of developing countries are recommended to take note of the PAG's advice on national nutrition strategies: and they are advised, where social and economic conditions are such that proprietary infant foods can make little useful contribution, that serious consideration should be given to ending their importation, distribution, and/or promotion.

Astronomers meet administrators

Edward Phillips

THE discussion meeting on astronomy policy arranged by the Royal Astronomical Society in conjunction with the Science Research Council (SRC) turned out to be a staid affair than might have been anticipated, probably because the most vociferous critics of British astronomy are working outside the United Kingdom. There were no outbursts à la Burbidge or Evans. Nor were Sir Fred Hoyle, who two years ago seemed to have fallen foul of British astronomy politics, or Professor Ray Lyttleton, who has been a critic of astronomy policies, at the meeting.

And with the meeting being held in the afternoon of Friday March 1, when the final election results were still coming in, the gathering was mindful of pre-election prophecies that a no-result election would be bad for the economy and therefore bad for big science. The main SRC representatives, Sir Eric Eastwood (Chairman of the Astronomy, Space and Radio Division) and Dr H. Atkinson (Head of the Astronomy, Space and Radio Division) made furtive glances at a blackboard showing the latest election figures whenever anyone mentioned expensive projects.

The election notwithstanding, Dr Atkinson was hopeful that the budget for the Astronomy, Space and Radio Board during the coming financial year will be about £20 million (something less than the cost of making one Concorde), divided up as follows: £4.7 million as the subscription to the European Space Research Organization (ESRO), £2.2 million for minor grants, £2.8 million for SRC establishments such as the Appleton Laboratory and £10.3 million for major facilities such as the projected Mark VA radio telescope for Jodrell Bank, the Northern Hemisphere Observatory (still no site fixed), an infrared flux collector, the Isaac Newton and Anglo-Australian telescopes, and various satellites, rockets and balloons.

The main news to report was that the two crucial committees of the board, the Astronomy Policy and Grants Committee and the Space Policy and Grants Committee, are soon to be folded up. Instead of these two committees which divide the board's parish on the basis of the technique used—astronomy that makes use of satellites would come under the space committee, for example—the SRC is to establish three committees whose interests are defined in scientific terms. An Astronomy I committee will concern itself with radio, X-ray and γ -ray astronomy and with cosmic rays, high energy astronomy in other words. Astro-

nomy, including optical, infrared and ultraviolet astronomy. A Solar System committee will be interested in the Sun, Moon and planets, in solar-terrestrial relations, the Earth's ionosphere and so on. Astronomers will be waiting to see whether new arrangements prevent the perennial research council disease of grant applications falling between two committees.

The meeting also heard that some decision on the much-discussed Northern Hemisphere Observatory is expected this autumn. Professor D. W. N. Stibbs, Chairman of the Astronomy Policy and Grants Committee, said that the SRC is thinking in terms of having three telescopes at the observatory, with apertures of $1\frac{1}{2}$, $2\frac{1}{2}$ and $4\frac{1}{2}$ metres, the largest one possibly having an altazimuth mounting. With Tenerife now

Musical chairs again?

JUDGING from recent advertisements, the British astronomical community is once more to be thrown into turmoil. Four posts are available at the University of Sussex from October 1974, an unspecified number of "positions" at the Institute of Astronomy in Cambridge from the same date, and Professor H. Brück's retirement will, a year later, result in the appointment of a new Astronomer Royal for Scotland and Regius Professor of Astronomy in the University of Edinburgh. No doubt astronomical administrators must also have it in mind that the caretaker Director of the Royal Greenwich Observatory (RGO) also reaches retiring age in the not too distant future.

In recent years, there has been a remarkable shuffling of astronomers around Britain, in some cases back and forth between the same universities; a possible conclusion to be drawn from these musical chairs is that there is a lack of talent at the highest levels. It is certainly difficult to think of two people both acceptable to the establishment and willing and able to handle the jobs at the RGO and Edinburgh. It might be worth reflecting on the possibility that the insecurity engendered by the appointment of researchers for "one, two or three years", and the resulting shuffling sideways at frequent intervals, could be one contributory factor in discouraging the development of sufficient talent both able to do the top jobs and willing to stay in Britain.

apparently out of the running for political reasons, the choice of site seems to be settling down to either Hawaii or Madeira, the Atlantic Island belonging to Portugal. Professor Merle Walker of Lick Observatory, California is acting as a consultant for the SRC during the selection process.

The decision between the two sites seems to be finely balanced. Seeing conditions are generally accepted as better on Hawaii, but by how much better is uncertain, and with the cost of an observatory on Hawaii being higher than Madeira it may yet turn out that, photon for photon, Madeira gives better value.

In the past the Science Research Council has had a reputation for keeping its ideas to itself until much too late in the day. The holding of this special meeting was therefore held to be a step in the right direction, even though it was noted that in the case of the reorganisation of the committee structure the decision had already been taken. Some participants, notably Professor Tom Kaiser (University of Sheffield) wanted even more disclosure of the way the SRC goes about its business and Professor Martin Rees suggested that there be a series of smaller follow-up meetings to discuss particular aspects of the SRC programme.

Water storage in the Wash

Eleanor Lawrence

SINCE 1965 the Water Resources Board has been investigating the possibility of freshwater storage in the Wash estuary on the east coast of England. The board has recently published the interim report on the feasibility study for a proposed scheme costing £140 million, which, if implemented, will eventually provide a major new source of water for the heavily populated south-east corner of England.

A desk study completed in 1970 decided that at present a full barrage enclosing the Wash was technically impossible but authorised a practical study of the first stage of a scheme in which freshwater from the rivers Great Ouse, Nene, Welland and Witham, which flow into the Wash, would be pumped into a system of three or four artificial reservoirs built just offshore. This feasibility study, which includes an ecological survey and the construction of trial embankments, is expected to cost £2.6 million over about six years.

The area has now been completely mapped by aerial, hydrographic and land surveys. And three sets of models are under construction at the Hydraulics Research Station at Wallingford to

study conditions likely to arise from building structures in the Wash and taking water from the inflowing rivers. Geological and geophysical surveys are now complete and have not revealed any major problems.

A trial inshore bank (the bank bounding the landward side of the reservoir) was successfully completed in 1972 and showed that it would be possible to construct the banks using hydraulic fill piped from the existing foreshore sediments. This bank was built entirely from the land and it was intended to construct a trial offshore bank during 1973. In the event no suitable tender was received and so construction was postponed. In view of the present financial position, however, this proposal is being completely re-examined by the government and may be cancelled, especially in view of the board's recommendation that the Wash scheme need not be considered for development until the late 1990s.

Apart from this, the other major outstanding item is the programme of hydraulic model tests. This should be completed by 1975, says the board, and it should then be possible to pronounce on the feasibility of the first stage of the scheme, a reservoir covering 1,700 acres near the mouth of the Great Ouse.

Ecological surveys coordinated by the Natural Environment Research Council have been continuing since 1971. The Wash covers 232 square miles and contains some of the finest salt marsh and mud flat habitat in Britain. The Ouse Washes which are most likely to be affected by the development have been designated by the Nature Conservancy Council as of grade I scientific interest and are included in a register prepared by the International Union for the Conservation of Nature as being of outstanding significance.

The Wash itself is one of the most important breeding and feeding grounds in Britain of the Common Seal which, despite its name, is not so common now. As their main feeding grounds are in the outer Wash, seals are not likely to be affected by development, at least in its initial stages, unless salinity changes affect the type and abundance of food species.

The surrounding mud flats are a particularly important feeding ground for overwintering waders and wildfowl. Monthly counts suggest that the number of waders centred on the area can reach 300,000. One of the four proposed sites for the first reservoir, Bulldog Sands to the east of the mouth of the Great Ouse, is one of the largest feeding grounds for the wading birds whereas another, on the west of the river mouth would be less acceptable to the shellfish industry, which produces about £250,000 worth of various shellfish from

the Wash each year.

Final conclusions on the feasibility and siting of the reservoirs must await the results of the hydraulic model tests, final costings and the possible construction of the offshore bank. The report promises that ecological considerations will be taken into account and the Nature Conservancy Council plans to publish a separate report on overall conservation when the final results of the engineering studies are known.

Physics for physicists

John Hall

PROFESSOR Frederick Guthrie founded the Physical Society in 1874 "for showing new physical facts and new means for showing old ones, for making known new home and foreign discoveries", and one of his regular teaching aids was a compartmentalised box containing specimens of the actual insects, minerals or materials which were the subjects of his lessons. The point was that any number of descriptive talks on, say, cotton spinning, fell short of the mark if a pupil simply had no clue about the appearance, the textures, indeed the nature of raw cotton. These object boxes (origin of the term 'an object lesson') are among the early exhibits in a display of physics memorabilia forming the exhibition "Phonographs to Holographs" at the Science Museum, South Kensington, in honour of the Physical Society's centenary. (Incidentally, one of the historic object boxes pictured contains, under the heading "butterflies", a creature which bears a remarkable resemblance to a Cinnabar moth; but the spirit of the thing was clearly progressive.)

The exhibition runs to an engaging range of Victorian laboratory machines, resplendent in brass and mahogany, and

throws on a number of distinguished investigators sidelights which never made the pages of a text book; Sir William Thomson, for example, is characterised not only as a designer of precision electrical instruments but also as the inventor of a patent water tap. What's more, a good many of the old masters' experiments are reproduced as working models, in the museum's push-button tradition, though the precise value of the demonstrated principle is not always made clear. Kelvin's water dropper, for example, is a pleasant enough looking contraption which intermittently interrupts two streams of water, sends out a spray of droplets and emits a blue spark. An attached rubric explains that this electrostatic induction machine had no practical application, although it led to the design of the Replenisher and the Mouse Mill Generator. Which is all very well if you are acquainted with mouse mill generation, and know its significance (or otherwise).

In fact, as soon as the Victoriana has been digested, the exhibition is plainly a display for the specialist, and calculated to suffuse the museum's staple school-boy customer with indifference. The explanation of the Josephson effect might well have been written in a foreign language and when a layman looks at a superconducting solenoid it does not really help to know that it has a field of 5.4 tesla with a current of 2,300 A. It does not even help to be told that you are looking at a superconducting solenoid. Similarly, two historic pieces of apparatus from the Cavendish Laboratory fall on stony ground if you have not the first idea of what bombardment means, or why it is nice to see the paths of atoms traced in a cloud chamber. C. T. R. Wilson's cloud chamber, described by Rutherford as "the most original and wonderful instrument in scientific history" does not begin to look as though it deserves such a testimonial, and neither does the written explanation supply a justification. A group of youngsters perusing the show on opening day gave about five seconds each to telephones through which one could hear the voices of Wilson and Rutherford describing their work. Five seconds was really not long enough to catch their drift but it was just about long enough to establish that you did not really understand what they were talking about.

So, if you are a physicist, this is an exhibition which you will discover to be packed with nostalgic gadgetry (*pace* Wilson and his cloud chamber) and if you are not a physicist it is an exhibition which tells a tale of the sound and the fury (disintegrating the nucleus of an atom surely qualifies for that description), but may not signify too much. The title of the show springs

from the fact that during the first decade of its existence the most striking foreign discovery that the Physical Society saw was Edison's phonograph; a highlight in recent times was a demonstration of Gabor's Nobel prize-winning holograph. And there at the entrance to the exhibition sits a holograph of Gabor himself, looking for all the world like a Tussauds version of the multiple murderer Reginald Christie. Two more exhibits which deserve mention as eye-catching and reasonably self-explanatory spectacles are a scanning electron microscope (the Cambridge Stereoscan 600, whose blown-up pictures would have looked all that much better in colour) and a pair of motorised mirrors which track back and forth on rails in an experiment measuring the velocity of light. On the whole, this exhibition supplements Rutherford's definition of all science being either physics or stamp collecting. It is also semantics.

First Australian-Soviet science agreement

Peter Pockley, Sydney

THE first agreement between Australia and the Soviet Union for cooperation on science and technology was initiated in Canberra at the end of February. At this stage the formal agreement has been expressed only in the most general terms.

A delegation of three Soviet science administrators paid a preliminary visit to Australia to discuss possible projects of cooperation. The Soviet delegation was at a high level—representing the State Committee, USSR Council of Ministers for Science and Technology were Mr L. N. Yefremov (First Deputy Chairman) and Mr V. A. Kuzin (Head of the Department of Foreign Relations); representing the USSR Academy of Sciences was Mr S. G. Korneev (Chief of the Directorate of Foreign Relations).

The agreement is seen as a quiet first, but significant, step in the Australian Labor government's diplomatic moves to equalise, as far as possible its formal relations between the western, eastern and Asian blocs. Australia has had a binational agreement with the United States for scientific and technical co-operation since 1968. Australian science also has strong links with Britain through the Anglo-Australian Telescope Board and a cooperative programme with Japan for its geostationary meteorological satellite is being evaluated. Soviet and Australian scientists will now work towards the signing of a detailed agreement in Moscow later this year. The Australian Department of Foreign Affairs has recently appointed its first

Senior Adviser on Science, Technology and the Environment, Mr Guy Gresford, an Australian who was formerly Director of Science and Technology at the United Nations.

Linear motors and the EEC

John Wilson

EIGHT manufacturers of linear motors met recently in Brussels, at the request of the Commission of the European Communities, to work out joint proposals for the development of a high power motor suitable for a fast European inter-city transport system.

The companies, representing France, West Germany and the United Kingdom, outlined suggestions for future research but also indicated that the commission must identify the objectives of such a programme more precisely before close collaboration can begin. It is now up to the commission to assess the opinion of the various governments and transport authorities concerned and produce some formal proposals with which the manufacturers can come to grips.

The commission feels strongly that any inter-city transport system for the 1980s, which would involve travel at speeds $>300 \text{ km h}^{-1}$, should be planned on a European basis. Whatever means are used to support the vehicle—wheels, jets of air or magnetic suspension—a high power linear motor is the obvious choice for the traction unit as it overcomes the mechanical difficulties of transmitting sufficient force to the track.

The 'club' of manufacturing companies, including Tracked Hovercraft, General Electric Traction and Linear Motors, first met in June last year and expressed their readiness to embark on a cooperative venture. According to the commission, a good deal of quiet consultation took place afterwards, and that formed the basis of the recent proposals. These are that three cross-company research teams should study the synchronous, asynchronous and transverse-flux motors, respectively; another should examine the problems of collecting electric current at high speed; and a fifth should investigate control systems for the motor.

At first there would be some parallel development of all the motors until a particular type or types were chosen for construction. Then these would be built and tested to evaluate the design.

But these proposals represent a very cautious stage in the negotiations between the members of the club because, although the commission tentatively estimates that it will spend about £2

million on the research programme, over the next two years, no accurate costing has yet been attempted. The companies plan to contribute to the construction and other costs as the commercial stage of the project draws nearer but they hope that the commission will foot the entire bill until it is decided which type of motor will be developed.

There is also some concern that the various governments can reach agreement on the sort of system they want

as readily as the commission seems to suppose. There is little point in the United Kingdom taking part, for example, unless the channel tunnel is in operation. Most population centres in Britain are so close together that, after the introduction of British Rail's new Advanced Passenger Train, journey times are unlikely to be significantly improved.

Unlike an existing rail system, where an individual company can take considerable initiative in its improvement,

a new high speed network requires an enormous capital investment (in civil engineering costs alone) which places it firmly on a national, if not international, level. It seems surprising, therefore, that the commission has waited until now to begin consulting the potential users of the scheme. Without an agreed specification from the governments and others concerned, the technical collaboration of the companies, such as it is, will remain in a vacuum.

Population and politics

SIR,—The article "Is Population a Ministerial Responsibility?" is certainly a thought-provoking one, and makes the main point extremely clearly but it contains a statement which I think should not be allowed to stand unquestioned—that is, "the current demographic position in Britain is that no serious economic or social problems which could be directly attributed to either its population size or growth rate are likely to emerge in the next 30 or 40 years". Further on Mr Cope points out that the Population Panel had argued the necessity of bringing home to the public the need to consider the aggregate consequences of their family building behaviour, in spite of the possible conflict of these consequences with individual preferences.

One point which immediately springs to mind is that, notwithstanding the very considerable publicity that has been given to the existence of family income supplements and similar benefits of this type, a large proportion of the group for whom they are meant are unaware of the existence of the benefits to which they are entitled, yet the limited evidence available in the report of the Population Panel suggests that this particular group, who form most of socio-economic group 5, are con-

sistently among those with the highest reproduction rate. Although there is clearly scope for a great deal of work in fields relating the family's economic status to family size as matters stand (and with the example of one difficulty in communication of a real need being all too apparent) it seems to me highly premature—if not completely wrong—to suggest that continuation of trends such as this could not give rise to serious social problems over the next 30 or 40 years. An equal problem may arise by the over-reaction to publicity of groups such as socio-economic group 1.

Cigarettes and guilt

SIR,—Although any contribution to the problem of deterring cigarette smoking by pregnant women is welcome, the airing given to it in your leading article of February 15 seems to me to need correction.

Your suggestion that a different approach would have been more effective and humane is not one which the careful preparatory work which we did bears out. A substantial survey of the reaction of pregnant women to the approach adopted, and a smaller one concerning the use of the naked figure, established quite clearly that the message and its form were entirely acceptable to those for whom it is intended. Conversely, much experience of the use, mainly by other organisations, of soft and pretty material has established that it is, as regards topics as serious and difficult as this one, largely ineffective. In-

cidentally, the effort we are making represents not only a new dimension in a continuing campaign against smoking in general; it is a specific effort to tackle the most clearly avoidable of all the factors affecting perinatal mortality.

The "well informed doctor and nurse" to whom you refer are a vital element in the campaign. Almost all the general medical practitioners and midwives in practice, and a great many clinic staffs, have received a personal letter setting out the scientific case for the campaign and inviting participation in exactly the way you have in mind, using our leaflet if they so wish.

Finally, of course we agree with your suggestion that information should be given to school girls about this topic and, indeed, several others affecting their health and well being. But this is a different exercise to which we are addressing ourselves as a separate activity.

Yours faithfully,
A. C. L. MACKIE

news and views

Fermi surface of magnetic rare earths

THREE physicists at the University of Birmingham have reported direct measurements of the Fermi surface of gadolinium metal (Young, Jordan and Jones, *Phys. Rev. Lett.*, **31**, 1473; 1973). This is the first experimental observation of the Fermi surface of a magnetic rare earth element, although there have been some preliminary measurements reported by workers at the Ames Laboratory in the United States on a sample of non-magnetic lutetium (Hoekstra and Phillips, *Phys. Rev.*, **B4**, 4184; 1971).

In a metal some of the electrons are lost by the atoms to the conduction band. If these electrons were perfectly free they would have a quasicontinuous range of allowed energies up to a maximum energy, the Fermi energy. The electrons move through the periodic lattice of the positive ions, however, and these cause the formation of allowed and forbidden energy bands. In anisotropic three-dimensional materials the energy bands are also anisotropic and the Fermi surface, the energy surface formed by the Fermi energy in three-dimensional reciprocal space, also becomes non-spherical. These concepts of band structure and Fermi surface are vital in understanding the magnetic, electrical and thermal properties of metals.

There have been several very careful calculations of the band structure (Keeton and Loucks, *Phys. Rev.*, **168**, 672; 1968; Jackson, *Phys. Rev.*, **178**, 949; 1969; Dimmock and Freeman, *Phys. Rev. Lett.*, **13**, 750; 1964), and hence the Fermi surface, of the rare earth metals. In particular the magnetic properties have been interpreted in terms of very small variations of apparently insignificant parts of the theoretical Fermi surface (Evenson and Liu, *Phys. Rev.*, **178**, 783; 1969). Obviously before more detailed theoretical calculations are started there has been a need for some supporting experimental evidence.

Problems have arisen, however, because techniques which allow measurements of the Fermi surface require very pure single crystal materials. It is only in these samples that the electrons can traverse reasonable distances of the Fermi surface without suffering scattering. The rare earths have proved difficult to purify for a variety of reasons. The elements in the series all have identical outer electronic structure and hence chemical separation is difficult. Relatively pure samples of rare earth oxide can best be obtained by ion-exchange techniques and the metal produced from the oxide by a conversion to the fluoride followed by a calcium reduction of the fluoride. Added to this the individual elements are highly reactive, readily forming nitrides, hydrides, oxides and carbides both during preparation and on subsequent exposure to the atmosphere. Until very recently samples more than 99% pure with respect to all constituents were very difficult to manufacture.

The Birmingham workers have used the technique of solid state electrolysis in ultra-high vacuum (UHV) to improve the purity of their gadolinium samples, particularly with respect to the gaseous and carbon impurities. The initial material is taken in the form of a polycrystalline rod and placed between electrical contacts in a UHV system. A current of 500 A cm⁻² is passed through the sample heating it to 1,100° C. The metallurgy of this process is not well

understood but it is thought that during the electrolysis the oxygen impurities among others migrate to the anode end of the sample, while the hydrogen is simply released in the UHV heating. Hence a section cut from the centre of the sample is found to be purer than the starting material. If this subsample is reprocessed the purity improves still further. An added advantage of this purification process is that preferential grain growth takes place in the centre of the rod, producing single crystals with dimensions of some millimetres.

A simple, though for the rare earths a sometimes unreliable, method of checking the purity of the materials is to measure the resistance ratio (the ratio of the electrical resistance at 300 K to that at 4.2 K). The higher this value the purer the sample. The resistance ratio for these latest Gd samples (240) is an order of magnitude better than for previous material. The Ames lutetium had a resistance ratio of 21.

The de Haas-van Alphen technique, in which on cooling the sample to about 1 K it is found that the magnetisation is periodic with increasing internal magnetic field, has been used to study the Fermi surface of the pure Gd. The frequency of the periodicity can be associated with the frequency of a particular electron orbit around the Fermi surface. Young *et al.* were able to observe four separate de Haas-van Alphen frequencies for a magnetic field applied in the base plane of the hexagonal structure and a further three frequencies for a magnetic field applied along the hexagonal axis.

The higher experimentally observed frequencies can be associated with orbits round the theoretically predicted Fermi surface. For example, the theoretical Fermi surface is basically columnar in shape and oscillations around the trunk of the column can be observed and the diameter of the column estimated. The lower frequencies reported cannot, however, be explained with the theoretical Fermi surface at present established. As happens at regular intervals in developing areas of research, it seems that the tables have been turned. Until this paper was published theoreticians were demanding measurements of the Fermi surface to check their calculations. Now the experimentalists would like more sophisticated theory to explain their results.

Of course, these pure samples of single-crystal rare earth elements will start a new series of measurements on those physical properties that depend on purity. Already Wells, Lanchester and Lee at the University of Southampton have measured the specific heat of Gd at low temperatures and found no evidence for the anomaly at 3–4 K reported by previous workers. This anomaly can now be clearly attributed to Gd₂O₃ impurity present in the previous samples.

Immunity to measles and canine distemper viruses

THE role of cell-mediated immunity in recovery from virus infection is a subject which is currently receiving considerable attention. It has long been recognised that dysgamma-globulinaemias—persons with deficiencies in their ability to produce humoral antibodies—recover normally from certain virus infections and can be immunised successfully against

smallpox. More recently, the key role of cell-mediated immunity in recovery from some of these diseases has been demonstrated experimentally by inoculating virus into mice whose ability to produce circulating antibody has been destroyed by the injection of cyclophosphamide. It now seems probable that, whereas recovery from enterovirus and arthropod-borne infections is due to the production of humoral antibody, recovery from herpesvirus, poxvirus and, possibly, myxovirus infections is largely a consequence of cell-mediated immunity, though cooperation between T and B lymphocytes has been demonstrated in several systems (see Allison, *Proc. R. Soc. Med.*, **66**, 1151-4; 1973).

The demonstration by Brown and McCarthy of a cell-mediated hypersensitivity reaction to canine distemper virus in dogs sensitised with measles virus (see page 344 of this issue of *Nature*) may throw new light on the nature of the immunity to distemper conferred by the inoculation of measles virus. Puppies born of distemper-immune bitches receive immunoglobulins in the colostrum and these not only protect against infection but also prevent successful immunisation with live distemper vaccine. Measles virus is not neutralised by distemper antibody and, provided sufficient is administered, can protect against subsequent challenge with distemper virus. Vaccination of dogs with measles virus may result in the production of some measles antibody but this has no neutralising effect on distemper virus *in vitro* and no distemper antibody is formed. This, together with the fact that protection is related to the dose of measles virus administered, suggests that the heterotypic virus functions in a similar way to the first dose of an inactivated vaccine, serving to stimulate a primary but not a secondary immune response (Prydie, *Vet. Rec.*, **83**, 554-9; 1968). On the other hand, a single dose of an inactivated vaccine does not usually produce a solidly-immune state and there is evidence that the efficacy of the vaccine is destroyed by treatment with formalin. Clearly, the mechanisms of heterotypic resistance cannot be satisfactorily explained on the basis of a humoral antibody response. The possibility that cell-mediated immunity may be the principal immune mechanism involved provides an exciting challenge for future study.

The work of Brown and McCarthy should also serve to stimulate further work on the mechanisms operative in recovery from canine distemper. There is considerable variation in the facility with which individual dogs recover from the disease and several attempts have been made to correlate recovery with the rate at which serum antibody is formed; it has been claimed that unless a neutralising antibody titre of about 1 in 100 (against 100-300 EID₅₀ in the standard *in ovo* neutralisation test), is present by the fourteenth day after infection, the dog is likely to succumb. This view fails to take account of the evidence that dysgammaglobulinaemic children recover uneventfully from measles. Moreover, the neutralisation test measures only those antibody molecules which have not yet complexed with virus antigen; in an animal whose tissues are still actively producing virus, a low neutralising titre does not necessarily imply a deficiency in the humoral antibody response because a proportion of the antibody formed will be complexed with virus. Clearly, much remains to be done before the relative importance of different types of immunity in recovery from virus infection is fully understood.

H.J.C.C.

Where do meteorites come from?

Nobody knows for certain where these large chunks of interplanetary matter come from. The ones that have been picked up from the Earth's surface have mineralogical and crystal-

lographical characteristics which were probably produced during the early stages of planetary formation. These meteorites all seem to be transient members of near space, however, their life times as individual entities, away from their parent body, being several orders of magnitude shorter than the age of the Solar System.

Present theories fall into three main categories. First, meteorites could have an asteroidal origin, being produced directly as fragments of colliding asteroids in the asteroid belt or from those few asteroids which happen to cross the orbit of Mars. Knowledge of asteroidal bodies is very sketchy, but their orbits can be found easily and their diameters can be estimated from the intensity of the reflected light and from very careful direct optical measurements. Masses, densities and internal structure (apart from the measurement of the mass of Vesta by Hertz (*Science*, **160**, 299; 1968)) have all been estimated by assuming asteroids are made of meteoritic material; so one is back to where one started from. Two problems rear their heads with this theory. The short period of exposure to cosmic rays—even if erosion sputtering due to collision with microparticles in the Solar System dust cloud is taken into account—implies a demand on supply that is several orders of magnitude greater than the mass of debris produced by asteroidal collisions. It is also very difficult dynamically to bring a particle from the collision position in the asteroidal belt into the inner Solar System. The mean relative collision velocity of asteroids is around 5 km s⁻¹ and an impulse of this order in the retrograde direction is required to change the orbit into one that intersects the Earth. The Mars asteroids are too few to yield sufficient debris.

Lunar ejecta has also been suggested as a source, but the mean geocentric velocity of this ejecta when captured by the Earth would be very low and also, because of pulverisation, large particles have little chance of survival. Öpik (*Adv. Astron. Astrophys.*, **4**, 301; 1966) calculates that about 0.2% of the meteorites have a lunar origin.

The third hypothesis has meteorites originating in comets. It must be remembered that as meteorites have such a short exposure age, their parent bodies must still exist and should be an observable class of celestial object. Stone and iron meteorites could come from cometary nuclei, the thick layers of icy conglomerate (in the Whipple model of the nucleus) shielding them from cosmic rays for most of their lifetime. The longer exposure ages of iron meteorites could be easily explained by the lower erosion rate of the surface of iron meteorites relative to stones. But there is little evidence of any correlation between meteor showers (which occur when the Earth goes through the toroid of dust debris produced by decaying comets) and the fall of meteorites. This could be due to the large gas pressure required to blow particles away from the gravitational attraction of the nucleus; in other words, large particles of the size of meteorites (> 10⁵ g) might never get away whereas the smaller visual and radio meteors (10⁴ → 10⁻⁵ g) do. Öpik finds that the biggest particles that can escape have diameters less than $17.3q^{-2}d^{-1}$ cm where q is the perihelion distance in astronomical units and d is the diameter of the nucleus of km. Comet Encke could therefore lose metre-sized chunks and large meteoritic fragments have been associated with the Taurid stream which originated from Encke. Of course the cometary origin still leaves the question of how the meteorites got into the nucleus in the first place.

One way of deciding between these theories is to analyse the structure of meteorites in more detail, hoping that additional knowledge might provide the vital clues. Results of this type of detailed analysis have been put forward in three recent papers in *Science*. MacDougall, Rajan and Price of the Department of Physics, Berkeley, University of California have found (183, 73; 1974) that the individual grains and chondrules in gas rich meteorites have high densities of particle tracks and severe track density gradients caused by low energy particle irradiation from nuclei accelerated by

solar flares. This irradiation damage was also non-uniform. They find that track density gradients exist not only on the particle surfaces but also at internal broken edges in the meteorite, indicating that the meteorite compacted more than 10,000 years after the grains were formed. The gradient is also so steep that only a very tenuous atmosphere ($\lesssim 10^{-8} \text{ g cm}^{-3}$) could have intervened between the Sun and the meteorite. The non-uniformity of the irradiated features of the meteorites Kapoeta and Fayetteville are similar to those found in lunar soil. Grains also seem to have been shocked after formation, possibly during meteorite compaction.

Brownlee of the Department of Astronomy, University of Washington and Rajan have found (182, 1341; 1973) micrometeorite craters, caused by hypervelocity impacts ($>4 \text{ km s}^{-1}$), on the chondrule-like spherical objects in the meteorite Kapoeta. These craters are very similar to those found on lunar glasses. By comparing the meteorite with lunar materials, the authors conclude that the micrometeorite flux in the past was about an order of magnitude higher than it is at present, and that the chondrule spheres are droplets of once melted ejecta produced by cratering events on the parent body of Kapoeta. The rarity of these spheres in comparison with their relative abundance in lunar soils indicates that this parent body is of asteroidal size. Brownlee and Rajan conclude that the meteorite Kapoeta was formed by impact processes on an impact-generated regolith, this regolith being on an asteroidal-sized body; and that this process occurred during the latter stages of the accretion mechanism that formed the planetary bodies of the Solar System. It has also been found that the physical properties of interplanetary dust have not changed appreciably over the lifetime of the Solar System even though the flux was higher in the past. This implies a long term constancy of cometary phenomena in the inner Solar System.

Lange and Larimer (Center for Meteorite Studies, Arizona State University) have also been looking at chondrules (Science, 182, 920; 1973), this time in the meteorite Ngawi. They conclude, however, that they were formed by flash heating and remelting of dust grains caused by high velocity ($1\text{--}10 \text{ km s}^{-1}$) impacts in the cooling gas nebula that formed the Solar System.

It seems that chondrules could be formed right at the beginning of the Solar System or on the surface of an asteroid. Also the upper limit to the atmospheric gas pressure at the meteorite surface calculated by MacDougall, Rajan and Price does not exclude a cometary nucleus as the source of meteorites (do not forget that this nucleus is also being bombarded by interplane-

tary particles). So even now all the options are open and the origin of meteorites is still a mystery.

D.W.H.

Activation of latent leukaemia viruses

from a Correspondent

IN 1970 Hirsch, Black, Tracy, Leibowitz and Schwartz (Proc. natn. Acad. Sci., U.S.A., 67, 1914) reported that graft-versus-host (GvH) reactions in BALB/c mice activated leukaemia viruses that otherwise remained latent or repressed. Hirsch and his colleagues then proceeded to demonstrate leukaemia virus activation during homograft reactions provided that immunosuppressive agents were also administered (Science, 180, 500; 1973) and in mixed lymphocyte reactions *in vitro* (Proc. natn. Acad. Sci., U.S.A., 69, 1909; 1972). Since stimulation of lymphocyte proliferation by mitogens such as phytohaemagglutinin did not activate leukaemia viruses, these authors concluded that virus activation requires specific immunological stimulation.

Could the activated virus be responsible for the high frequency of lymphoreticular tumours found in mice undergoing chronic GvH reaction? Armstrong,

Black and Richards (Nature new Biol., 235, 153; 1973) found that ultrafiltrates of spleens from mice undergoing GvH reactions induced leukaemia when inoculated into newborn mice. It is also well known that New Zealand Black (NZB) mice which suffer spontaneous autoimmune disease have a high level of endogenous leukaemia virus activity and a high incidence of lymphoreticular tumours.

It is becoming evident that the leukaemia viruses associated with chronic immune reactions in mice have a peculiar host range. They can neither be classified with the N-tropic nor B-tropic murine leukaemia viruses because mouse cells themselves are resistant to infection whereas certain cells of other species are susceptible. The virus of NZB mice has been studied by Levy and Pincus (Science, 170, 326; 1970) who found that it is non-infectious for mouse cells but infects rat cells. Levy now reports (Science, 182, 1151; 1973) that similar viruses can be isolated from normal spleens and kidneys of NIH-Swiss and C57BL mice. These tissues were co-cultivated with non-producer NRK cells transformed by Harvey strain murine sarcoma virus, whereupon a pseudotype of the sarcoma virus was produced. This pseudotype infected NRK cells and possessed similar biological and immunological properties as the pseudotype obtained with virus from NZB mice. Immunosuppressed NIH-Swiss mice tissues gave rise to the highest titre of pseudotype. Scherr, Lieber and Todaro in the first issue of Cell (1, 55; 1974) report that a virus activated in BALB/c cells *in vitro* during mixed splenocyte reactions does not infect mouse cells but replicates most efficiently in a rabbit cell line. This virus is probably closely related if not identical to the viruses isolated by Levy. Thus a virus can be vertically transmitted in one species but when activated may only be able to infect cells of other species. Levy calls such viruses "xenotropic".

Another example of xenotropism is the endogenous feline virus which when activated replicates in human cells. This virus was originally detected after inoculation of RD cells, derived from a human rhabdomyosarcoma (McAllister *et al.*, Nature, 235, 3; 1972), into foetal cats *in utero* (again, an immunologically undeveloped host) and was at first regarded as a possible human virus (see Nature, 244, 252; 1973). A similar experimental model was used by Todaro *et al.* (Proc. natn. Acad. Sci., U.S.A., 70, 859; 1973) to isolate a virus from NIH Swiss mice which had been immunologically suppressed with antithymocyte serum and inoculated with RD cells. This virus, AT-124, contains group-specific antigen and RNA-dependent DNA polymerase related to murine C-

Vegetable anatomy

At first glance, few readers would associate this figure with Indian hemp, cannabis or *Cannabis sativa*. It shows, however, the anatomy of parts of this plant (for example, the epidermis of a bract) and is included in a new reissue of an atlas of microscopy published "for use in the identification and authentication of some plant materials employed as medicinal agents" (Powdered Vegetable Drugs by Jackson and Snowden; Thornes, London, 1974, £4.00).

type viruses but grows preferentially in cat and primate cells and not in mouse cells. It remains to be elucidated whether this xenotropic murine virus is identical to the immunologically-activated virus. The presence of a transplant from a permissive host in an immunosuppressed recipient provides ideal conditions for the proliferation of xenotropic viruses.

It can hardly have escaped the attention of any of these investigators that human leukaemia viruses, if they exist, might be activated by chronic immunological reactions or by immunosuppression. Such a virus could account for the increased incidence of lymphoreticular tumours found in patients suffering autoimmune disease or carrying organ transplants. Since nobody has yet cried "Eureka", one must assume that mixed human lymphocyte cultures do not activate leukaemia viruses as readily as those of BALB/c mice. This is perhaps not surprising since Hirsch *et al.* found that the immunological activation of murine leukaemia virus could not be observed with all mouse strains. Furthermore, if the activated human virus were

also xenotropic, its discovery may depend on finding the appropriate foreign cell type in which to grow the virus to detectable levels.

Alpha clustering inside nuclei

from our Nuclear Theory Correspondent

MANY different lines of evidence indicate that the nucleons in the nuclear surface tend to group together to form α particles. The cross sections for the elastic scattering of α particles by nuclei and of α -transfer reactions require a significant degree of α clustering. Hartree-Fock calculations of the structure of light nuclei show a pronounced tendency to form groups of four nucleons that can be interpreted as α clusters.

A new approach to the problem of α clustering in nuclei has recently been made by Brink and Castro (*Nucl. Phys. A216*, 109; 1973). They were primarily interested in finding out whether there is any tendency to α clustering in the interior of heavy nuclei, so to simplify their calculations they considered infinite nuclear matter so that all surface and Coulomb effects could be neglected.

Two types of infinite nuclear matter were dealt with: one consisting of nucleons represented by plane waves and the other consisting of groups of four nucleons (α clusters) in a regular crystalline array. If a particular form of the nucleon-nucleon interaction is assumed, the total binding energy of the system may be calculated by standard quantum mechanical procedures. It is then possible to see whether the array of α particles is more stable than the nucleons and this in turn has implications for the structure of finite nuclei.

In such a calculation the results must not depend too critically on the assumptions made, so Brink and Castro used two extreme types of nuclear force (the Brink-Boeker and the Skyrme) and three types of crystalline array (the simple, body-centred and face-centred cubic lattices). In each case it was found that for the nucleon densities corresponding to those in the centre of heavy nuclei the nucleon matter was more stable than the α -cluster matter. This suggests that the α clustering inside heavy nuclei is rather small.

For a series of different nucleon densities, it was found that when the density is reduced to about one-third of that inside heavy nuclei the α -cluster matter becomes more stable. Thus as the density of nuclear matter is reduced there comes a point where it condenses into α particles. This is to be expected from the high binding energy of the α particle and the condensation takes place as soon as the density is low

enough to prevent the interactions with all the nearby nucleons from breaking up any incipient clusters that may be formed.

The actual density at which the condensation occurs naturally depends on the nuclear force and on the form of the crystal lattice assumed in the calculation; but since the ones used were deliberately chosen to be rather extreme, any other realistic force or lattice will give results similar to those already obtained. Thus the general conclusion is not affected by the details of the assumptions made in the calculation.

It is natural to apply these results to the nuclear surface, where the density falls rapidly to zero, and to infer that in the outer region where the density is low some degree of α clustering will occur. This argument is very plausible qualitatively, although the complications of a finite system with a curved surface and the presence of the Coulomb interaction alters the value of the critical condensation density. Nevertheless this work has shown in a simple way that we may expect to find some degree of α clustering in the nuclear surface, but not in the interior.

Skeletonising the polypeptide

from a Correspondent

PROTEIN crystallography has progressed so rapidly in recent years, and so many new structures have been solved, that speakers at current meetings in the field generally give little information on how their results are actually obtained, that is, the pure mechanics of the business. They rather prefer to persuade the audience of the specific and general biochemical significance of their latest elaborations, beautiful atomic models in wire or ball-and-stick, photographed and presented stereoscopically. For the more traditional crystallographer in the audience, well aware as he is of the overriding biological aim of protein work, the implication that his métier is, though important, somewhat humdrum and routine, strikes a hollow note.

It is refreshing, therefore, to come across new papers which re-emphasise the enormous difficulties still to be overcome in the analysis of a structure as complex as a protein crystal, and which introduce new techniques for tackling these difficulties. Increasingly, computers have been used, and, if heavy-atom derivatives of the protein can be prepared and suitable automated X-ray diffraction apparatus is at hand, then there are many programs available to prepare the data and calculate the three-dimensional Fourier synthesis of electron

Crustaceorum Catalogus

THE Pinnotheridae (Decapoda, Brachyura)—the crustacean family whose members are commensal or parasitic—are on file in the latest part of the *Crustaceorum Catalogus* (part 3, edit. by Schmitt, McCain and Davidson; Junk, The Hague, 1973, 76 Dutch guilders). The catalogue is basically a compilation of the references contained in the pinnotherid sections of two card files started by Schmitt in the Smithsonian Institution, Washington. All pinnotherid references to 1968 and a few more recent publications are included.

density. The problem that remains, that of assigning a polypeptide chain to the electron density, can involve many months of painstaking model-building work, and has hitherto been relatively unassisted by computer methods.

An important mechanical aid in model construction incorporates a half-silvered mirror, placed between the model and a plot of the electron density on perspex sheets, and arranged at such an angle that the model and the map appear superimposed to the viewer. This simple but ingenious device, called after its inventor, Professor Frederic Richards of Yale University, the Richards' box (by those in the trade, it is known more familiarly and affectionately as 'Fred's folly') has proved an indispensable aid. Even so, much experience and knowledge is required by the crystallographer to unravel and interpret the electron density map, and the prospect of programming a computer to take over this human task is daunting. Nevertheless, Greer (*J. molec. Biol.*, 82, 279; 1974) has presented a method which goes a long way towards the solution of this problem.

Often, the amino acid sequence of the protein is known and this greatly assists the interpretation of the electron density map. The more clearly recognisable residues in the map may be correlated with the sequence and the more obscure ones inferred by extrapolation. To make the situation more general, however, Greer eschews the use of sequence information. Instead, he aims to produce a skeleton outline of the polypeptide chain by progressively chipping away at the density map.

The electron density map, of resolution between 2 and 3 Å, is plotted on a Cartesian grid of spacing about 1 Å. Certain criteria are established for the selection or rejection of points on the grid. A point is removed if its density is in the interval being examined in the current 'pass' through the map, and if no 'hole' is created by its removal. To test for the latter condition, the relative densities of the 26 nearest-neighbour grid points were examined. Further prerequisites for removal are that the point should not be at the 'tip' of a density region (for example, at the end of a side chain) and that the removal should not destroy the continuity of the skeleton (this requires a search of nearest-neighbour relationships).

An illustration of the application of these rules is given for a simulated two-dimensional map representing a polypeptide of thirteen residues. In order to isolate the main chain, the side chains, defined in each case as the skeletal piece between a 'tip' and 'branch point', are removed and their positions flagged. An exception to this procedure has to be made at the end of the main chain,

defined by the coincidence of two side chain branches to a single branch point, since it is not known at this stage which is the main chain and which the terminal side chain. Main chain cross-bridges, due either to disulphide bridges or to hydrogen bonds are recorded.

The next major problem is to isolate a single molecule from its neighbours. The boundary is often poorly defined in the map and there may be considerable interpenetration of adjacent polypeptides. To eliminate unwanted chains, the symmetry operators and unit cell translations of the crystal are applied to each point or group of points to check whether it occurs more than once in the volume defined for one molecule. The redundant points are then chosen as those furthest from the centre of gravity of the molecule. There may still be unwanted pieces of neighbouring molecules present after this procedure, and the program searches for and eliminates all small chains that have both ends more than about 4 Å from any point on the skeleton. To reinstate portions of the main chain that may occasionally be deleted by mistake, the skeletons before and after the above procedures are compared, and the chain is examined for continuity.

The skeleton now represents the main chain punctuated by main chain branch points and side chain markers. These junctions indicate the positions of some of the α -carbon positions, and others

can be found by invoking the so-called 4 Å rule, that the separation of residues along a polypeptide chain is always about 4 Å. Greer is developing methods for further automation of the map interpretation, but meanwhile the existing program already provides a head start for further model-building work by conventional techniques.

The program is applied to the 2.0 Å map of ribonuclease S, for which the structure is well established. A certain amount of manipulation is required to optimise its performance, but the net result is a set of residue positions which strikingly resembles that achieved by conventional methods. The mean deviation of measured and predicted α -carbon positions is 1.37 Å, which indicates good agreement since the skeleton was calculated on a 1 Å grid. The skeleton shows features such as the β -structure regions and the disulphide bridges clearly, but there are some trouble areas. Occasionally, three, four or five-membered rings occur instead of a straight chain, but these features are easy to detect and eliminate. Sometimes small pieces of chain are missing where the density of the map is low.

The comparative layman may easily be misled by the elegance and apparent ease with which computer techniques can produce seemingly convincing structural models of dazzling complexity, and it is necessary to be especially critical of the predictions made. In this paper

Sunspots affect Indian monsoon

EVIDENCE that the solar cycle produces a marked effect on the weather on Earth continues to accumulate. King's recent study (*Nature*, 245, 443; 1973) gathered sufficient evidence that there could remain little doubt of the reality of the effect; a report by Jagannathan and Bhalme emphasises that this effect is a major one, altering the circulation patterns of the terrestrial atmosphere significantly.

This evidence comes from a study of variations in south-west monsoon rainfall in India between 1901 and 1951 (*Mon. Weath. Rev.*, 101, 691; 1973); the polynomial trend analyses and power spectrum analyses used reveal "composite patterns corresponding to the epochs of sunspot maximum, sunspot minimum, sunspot increasing and sunspot decreasing". The authors mention that 1899 was a year of severe famine on the Indian plains, brought about by extreme drought conditions, and that 1917 was a year of

very heavy rainfall. No doubt students of the link between solar cycle and the weather will be intrigued to note that these were years of minimum and maximum solar activity, respectively; although Jagannathan and Bhalme do not specifically mention the present serious droughts in India, it seems difficult to avoid the conclusion that these may therefore be linked to the present period of low solar activity.

That would certainly fit the "composite patterns" noted; it seems particularly unfortunate that the link and these patterns were not discovered sooner, when they might have provided forwarning of the present situation. But it is unlikely that such warnings would have been taken seriously a few years ago; it is to be hoped, however, that research into these climatic variations will be accorded the recognition which the progress now being made justifies.

the firm results are the proposed α -carbon positions, and the correspondence of these to the known positions of ribonuclease S is convincingly demonstrated. It will be exciting to see the method applied to a completely new and unknown polypeptide or protein.

New structure, new mechanism for trypsin

from a Correspondent

It may well be true that protein and enzyme crystallography has passed its zenith. But many laboratories engaged in this activity still continue to produce results that are often interesting, and even important. As the number of structures unravelled continues to increase, particular emphasis is being placed on structure-function relationships as well as on correlations between members of enzyme families.

The serine proteases are all enzymes involved in peptide bond cleavage during the processes of digestion, and the structures of two of them, chymotrypsin and elastase, were determined by X-ray analysis several years ago. Stroud and his colleagues now report the details of their studies on inhibited complexes of a third such enzyme, trypsin. Inhibition of trypsin by diisopropylfluoro-phosphate proceeds irreversibly, to give a complex, DIP-trypsin, and Stroud, Kay and Dickerson (*J. molec. Biol.*, **82**, 185; 1974) have determined its three-dimensional structure, initially at low, and then at higher (2.7Å) resolution. It is notable that the overall folding of the DIP-trypsin molecule is topologically very similar to that previously observed in chymotrypsin and elastase; the overall identity of sequence between these three is only 24%. The active-site architectures are likewise closely related. DIP reacts uniquely with Ser 195 and the position of the γ -oxygen of this residue corresponds closely to that in acylchymotrypsin.

Trypsin is also specifically and reversibly inhibited by benzamidine, in a way that probably mimics arginine side chains in a specific substrate. Krieger, Kay and Stroud have also determined the structure of this complex, which they describe in an accompanying article (*ibid.*, 209). The siting of the benzamidine in the enzyme-binding pocket, has induced alterations in the geometry of this pocket so that, in particular, it has undergone a marked closure so as to 'sandwich' the aromatic ring of the inhibitor molecule in between several peptide planes.

From the comparison at neutral pH of the structures of these two quite different inhibited derivatives of trypsin, Krieger *et al.* attempt to obtain information concerning the mechanism of the

enzyme action. DIP-trypsin can be considered to be a model for the 'tetrahedral' intermediate widely accepted to be a covalent intermediate in the catalysis of serine proteases—whereas the benzamidine-trypsin complex may well represent a Michaelis complex (or indeed any other non-covalent intermediate, such as the often-suggested trans-conformation complex). Benzamidine is, in effect, a powerful competitive inhibitor for specific trypsin substrates, and it is quite reasonable to suppose that it binds in the same way as them. Moreover, the benzamidine-trypsin complex is stable at pH 8, when the enzyme is totally in its active conformation. Any observed change in the protein structure may then be solely attributed to the actual binding of the pseudo-substrate, and not to any shift in the balance between active and inactive conformations. The structure of active free trypsin remains to be solved, although Stroud *et al.* believe that DIP-trypsin should resemble it quite closely.

Insertion of benzamidine into the binding pocket involves the formation of a salt bridge with the β -carboxyl group of Asp 189, this residue accounting for the unique specificity of trypsin among the serine proteases for positively charged substrates. It is striking that this bridge is formed without any movement of the carboxylic acid, this residue being constrained by the tertiary structure. Any other substrate whose basic side chain has not the required length, will then, in forming the salt bridge, move the susceptible bond of the substrate away from its optimal catalysis position. The binding of benzamidine effectively induces certain changes in the active site, which in all favour rapid subsequent hydrolysis in the case of the specific substrates. The readjustment of the position of the most important residues of the enzyme when it binds a positively-charged substrate, may also explain the activating power of small amines for the hydrolysis of non-specific substrates.

It is worth noting that the charge-relay transfer mechanism involving the catalytic triad Asp₁₀₂, His₅₇ and Ser₁₉₅ proposed by Blow *et al.* (*Nature*, **221**, 337; 1969), for the acylation and deacylation of chymotrypsin, can also be applied to trypsin. Stroud *et al.* make use of the recent results obtained with α -lytic protease (an elastase-like serine protease), by Richards and his colleagues (*J. biol. Chem.*, **248**, 8306; 1973), using ¹³C magnetic resonance studies with selective labellings in suggesting that the proton acceptor is the aspartic acid, and not the histidine residue. The imidazole ring of this histidine, which remains neutral throughout catalysis, serves simply as a relay between the serine and the aspartic acid residues. It thus keeps

the carboxylate in a hydrophobic environment such that its pK is increased to 6.7. The advantage of this new scheme (which is at variance with hitherto widely accepted doctrine), is that it implies no charge separation during the formation of the tetrahedral intermediate; and is therefore on the face of it, to be preferred energetically.

Limited progress with quantum gravity

from a Correspondent

Most people would regard quantum theory and gravitation theory as two quite disjoint subjects; the first concerned with microscopic systems such as atoms, the second with objects of astronomical dimensions. Nevertheless, the marriage of these two unlikely bedfellows has fascinated a generation of physicists, for although quantum gravitational effects are deemed to be forever beyond the scope of direct experimental verification, the aesthetic appeal of a theoretical unification of these disciplines has always been compelling.

One of the driving forces behind research into quantum gravity is J. Wheeler (Princeton University), who has been visiting Britain during the past few weeks. His visit coincided with a conference on the subject held at the Rutherford Laboratory on February 15 and 16, and organised by D. Sciama (University of Oxford). The large number of participants testified to the extraordinary degree of interest in Britain for what is beginning to seem a theoretical obsession. With the sort of optimistic statements made recently by workers active in the subject, the conference might have been expected to produce convincing evidence of definite progress. In fact, it succeeded in generating a deep scepticism.

C. Isham (King's College, London) began with a review of the various levels of theoretical sophistication available to the would-be gravity quantiser, each level having its particular brand of ambiguities and problems. The presentation of technical results by M. Duff (University of Oxford) only served to confirm the extraordinary lengths which are necessary in order to make even minor progress. Pessimism mounted with evidence supplied by J. Taylor (King's College) that if gravitation is to be described by general relativity, then apparently it would be unrenormalisable in the usual sense familiar from quantum electrodynamics. That is, not only do infinite quantities appear everywhere in the theory, but they appear an infinite number of times for even the simplest type of process. Quantum gravity, said Taylor, "is dead".

If that is so, the subject was promptly resurrected by the following day with a series of talks by the 'fresh start' advocates. Adopting the philosophy that if the problems encountered on one level of the theory are insuperable, descend to another and start again, attempts were described in which the very structure of space and time are called to question. R. Penrose (Birkbeck College, London), supplemented by his student, G. Sparling, gave an account of his theory of twistors, but left a strong impression that the resulting formalism, whatever its intrinsic interest, is still very far from reality. A lot of comment was heard about starting from nothing and pulling all of physics out of a hat, but with no conceivable experimental framework to restrain their imaginations, the fresh starters continued to give the impression of drifting through a fairyland in which anything goes.

In marked contrast, work being carried out at less sophisticated levels does seem to be making some, if limited, progress. M. MacCullum (University of Cambridge) reviewed developments in quantum cosmology, which is an attempt to quantise the Universe considered (artificially) as a system with a small number of degrees of freedom. Undoubtedly the main attraction of the conference was a presentation by the indefatigable S. Hawking, now published in *Nature* (248, 30; 1974) on exploding black holes. This was based on recent work which shows that when quantised fields are examined in a curved space background metric, not itself quantised, remarkable effects such as the spontaneous creation of particles out of the vacuum may occur. According to Hawking, creation processes of this type would cause microscopic black holes to disappear in a burst of radiation. Exciting through this prospect may be, no plausible physical mechanism could be discerned which might lead to such a dramatic effect.

Last but not least, A. Salam (Imperial College, London) gave a most entertaining evening talk about almost everything, including evidence that the proton may have a finite lifetime, with all the consequences that may hold for the physics of the early big bang in cosmology.

Wheeler's own distinctive solution to the quantum gravity problem was described in his distinctive philosophical style to a packed gathering at King's College, London on February 27. Fortified with the belief that the ultimate equations of the Universe would reveal themselves by being "so beautiful and compelling" as to be obvious, Wheeler inclines to the view that space-time is built out of an underlying 'pre-geometry' in much the same way that elastic media are built out of atoms. Only the most tentative steps have been

made along this fascinating path, based on the notion that the underlying structure should allow description in the simplest possible terms—perhaps just the logic of a 'yes-no' decision. For John Wheeler, this is a jumping-off point into the realms of philosophy, for how is the decision to be made? The mind, which has always had an uneasy co-existence with the world of the quantum, occupies a central role in Wheeler's universe—a 'participatory' universe as he calls it.

Whether or not all this will eventually result in a type of unification of quantum theory with space-time or gravitation theory, that will satisfy the aesthetic tastes of the physicist, is anybody's guess. What does emerge from these discussions is first the rather practical point that the quantisation programme so far has very little to do with general relativity (the discussion is almost exclusively dominated by field theorists and particle physicists) and, second, that progress with a full theory of quantum gravity (or if necessary a restructured space-time) is unlikely to be achieved until much more understanding of quantum field theory at the less sophisticated level of the Hawking result has been achieved. But the last word should perhaps be Wheeler's: when asked whether a young student wanting to work on quantum gravity should be a relativist or a field theorist, he replied with careful deliberation that such a person would be better advised to find something other than quantum gravity to work on!

Regulating the amounts of RNA

from our
Molecular Genetics Correspondent

ATTEMPTS to define the systems which control transcription have for the most part concentrated on individual gene systems whose products can be identified. Yet equally important is the problem of how the cell adjusts the general amounts of synthesis of different classes of RNA in response to changes in its environment. That the relative extents of transcription of unstable (messenger) RNA and of the two classes of stable (ribosomal and transfer) RNA are set in response to growth conditions is well established in bacteria. The increased complexity of RNA synthesis in eukaryotic cells, together with the lack of mutants influencing the control of transcription, have made comparable studies more difficult with higher organisms. But in a study of mouse fibroblasts maintained in culture, Johnson, Abelson, Green and Penman now report (*Cell*, 1, 98; 1974) on the amounts

of different classes of RNA present in resting and growing 3T3 and 3T6 cells.

With both cell lines—each derived from the fibroblast but with different sensitivities to contact inhibition and therefore possessing different growth controls—the amounts of both rRNA and mRNA are greater in growing than in resting cells. With 3T3 cells, in conditions of growth, there is some 2.8 times more rRNA; with 3T6 cells, growing cultures display 1.6 times more rRNA than resting cultures. But the mRNA content increases to a greater extent with growth; in 3T3 cells the increase is 4.0 times and in 3T6 cells it is some 2.3 times compared with resting cells. Each class of cell therefore increases its mRNA content more than its rRNA content in response to conditions promoting growth, the extent of the increase being characteristic of the cell line.

When serum (containing fibroblast growth factors) is added to 3T6 cells maintained in the resting state, the cells enter a quasi-synchronous division, the first cells entering the S phase of DNA synthesis after about 11 h, so that the first divisions take place after about 24 h. During the transition from resting to growth state, amounts of both ribosomal and transfer RNA start to increase about 11 h after stimulation and then continue to accumulate in a strictly coordinate manner. But mRNA behaves differently, increasing much more rapidly; the ratio of mRNA to rRNA increases 50% in the first 6 h and ultimately doubles. The rate of protein synthesis follows the rate of mRNA synthesis.

These results raise several intriguing questions about the systems which regulate the general amounts of RNA in cultured fibroblasts. One obvious point is that, unlike bacteria which possess only one known RNA polymerase, in eukaryotic cells mRNA synthesis is catalysed by one enzyme in the nucleoplasm whereas rRNA synthesis is controlled by a different enzymatic activity in the nucleolar apparatus. At least two different enzymatic activities, located in different cellular compartments, must therefore be controlled if any changes are made at the level of transcription.

Although the content of mRNA doubles before DNA synthesis begins in the transition from resting to growth state, previous work has shown that the overall rate of synthesis of HnRNA (the nuclear precursor to cytoplasmic messenger RNA) does not increase by this time—this implicates some step in mRNA production subsequent to synthesis of the precursor as a control stage at which the level of mRNA may be controlled. And since the rate of protein synthesis increases in harmony with the increase in messenger content—that

is before the increase in ribosome content—ribosomes must be used more efficiently during this period; this is consistent with models in which the frequency of initiation of protein synthesis is established simply by the amount in the cytoplasm of messenger RNA.

Amounts of ribosomal and transfer RNA seem to be perfectly coordinated in fibroblasts, unlike the situation in bacteria in which the ribosome/tRNA content may vary over a ten-fold range. But since these two classes of RNA display different stabilities in the fibroblast, their coordinate amounts cannot be established at the level of synthesis; neither rRNA nor tRNA is stable in resting cells, where their half lives are different, and rRNA is stable in growing cells whereas tRNA is not—details of the stabilities of different classes of RNA, a critical parameter in constructing models for the regulation of their activity, are reported by Johnson *et al.* to be in preparation. But the apparent coordination of the relative contents of tRNA and rRNA must clearly require noncoordinate synthesis. And the general response of the cell to conditions which stimulate growth is to increase its capacity for protein synthesis, the level of mRNA relative to that of the ribosomes and tRNA itself increasing so that the cell makes a more efficient use of the protein synthetic apparatus. Establishing the mechanisms implicated in the control of and response to the different states of the cell represented by the division cycle is clearly fundamental to any understanding of cell development, emphasising the importance of studies such as these which cast a light on the general systems that regulate RNA production.

Role of terminal sugars in biological events

from a Correspondent

DURING the past few years glycoproteins have moved dramatically from the ignominious position they long occupied of taking up the last forlorn session on the last day of international scientific meetings, to the glory of fully fledged symposia. There is scarcely a biological phenomenon that has not been bombarded with every laboratory's collection of lectins. Another obligatory reagent for research at present is neuraminidase, the effects of which are legion: on the immunogenicity of tumour cells; on receptor sites for viruses, hormones and certain lectins such as wheat germ lectin which has weak affinity for N-acetylneuraminic acid residues or other lectins having sialic acid specificity, for example, from *Limulus polyphemus*; on cell-

cell interactions; on lymphocyte transformation, and so on.

The clear demonstration of a causal relationship between these various events and terminal sialic acid residues of glycoproteins or gangliosides is unfortunately less commonly obtained, though notable exceptions are binding of myxoviruses and certain lectins that clearly recognise this sugar and bind to it. Another candidate is the interaction of the natural peptide, tuftsin with polymorphonuclear leukocytes (Constantopoulos and Najjar, *J. biol. Chem.*, **248**, 3819–3822; 1973). The enhanced phagocytic capacity induced by tuftsin is abolished when cells are first treated with neuraminidase so raising the possibility that membrane sialic acid is the receptor site.

Perhaps the most convincing demonstration of a direct role of terminal sugar residues in the control of biological activity comes from Ashwell and his colleagues, who have shown that neuraminidase treatment of a large variety of soluble glycoproteins (including hormones) redirects these components from a normal circulatory pattern to one in which they are quickly cleared from the blood stream by sequestration in the liver. Ashwell and his collaborators have clearly identified receptor sites present on hepatocytes that recognise another terminal sugar, D-galactose, which is exposed as such after removal of sialic acid residues.

A possibly analogous situation is described by Sandford and her colleagues (*J. Immunol.*, **111**, 1071–1080; 1973) and may provide the explanation for earlier observations that the ability of a transplantable murine tumour to grow in certain foreign strains of mice is significantly reduced by prior treatment of the tumour cells with neuraminidase. Tumour cells treated with neuraminidase are rapidly killed by a naturally occurring antibody (probably 19S IgM) in the serum of resistant mice with specificity for newly exposed oligosaccharide terminals containing galactose residues.

The apparently widespread involvement of sialic acid terminals in biological activities, either directly or by virtue of a protective effect in 'hiding' other recognisable sugar terminals (galactose for instance), is a consequence of the ready availability of neuraminidases. Similar experiments using other glycosidases to point out possible functions of terminal sugars such as fucose have been hampered by the relative inaccessibility of active glycosidases of the required specificity. The recent report of Remold (*J. exp. Med.*, **138**, 1065–1076; 1973) suggests that it is only a question of time before other sugar residues are involved in biological events. Remold has studied the effect of the enzyme, L-fucosidase, on the interaction of macrophage inhibition factor (MIF) with its target cell.

MIF is a soluble glycoprotein of moderate size that is secreted by sensitised lymphocytes on exposure to antigen. It is so-called because of an ability to immobilise macrophages *in vitro*; macrophages are prevented in culture from migrating from the orifice of a capillary tube. The factor also performs other duties in enhancing the effector activity of macrophages in the immune response: for instance, in increasing their stickiness and phagocytic capability. It is relevant to point out that the carbohydrate unit of MIF seems to play a part in its activity since neuraminidase treatment inactivates MIF as shown 3 years ago by Remold and David. The unknown mechanism of action of MIF certainly involves as the first step, interaction of MIF with the macrophage surface. It is this step that Remold has now found to require intact fucose terminals on the glycoproteins of the surface membrane of the target cell.

First, guinea pig peritoneal macrophages, incubated *in vitro* with MIF in the presence of L-fucose at 100mM, fail to migrate as well as a control cell population and several other sugars have no effect. The inhibition by fucose is easily reversed by removing the sugar by dialysis. Second, when macrophages are treated with a specific glycosidase to remove L-fucose terminal residues from the surface, these cells do not respond to MIF but migrate normally. Clearly then the necessary fucose residues are part of cellular surface glycoproteins and are not part of MIF itself. Indeed MIF exposed to fucosidase in contrast to neuraminidase (or proteases) retains full biological activity. The inhibitory effect of fucosidase on macrophages is transient and the cells regain their ability to respond to MIF within a few hours, probably by replacement of the fucose-deficient surface membrane glycoproteins with complete molecules. The inference therefore is that the molecules containing receptor sites for MIF on the macrophage surface contain L-fucose residues and are manufactured by the macrophage population. Since L-fucose alone is inhibitory only at high concentrations, it seems likely that MIF recognises an extended oligosaccharide sequence terminating in an L-fucose residue in the receptor site on the macrophage surface.

The identification of this sequence and the question of whether it exists on a unique glycoprotein species of the macrophage surface, or alternatively if MIF will recognise a terminal L-fucose residue attached to any penultimate sequence remains to be determined. The competitive effect of L-fucose binding lectins on the activity of MIF would also be of interest and no doubt is under active study.

GENERAL BOOKS

Evolution and God

Darwin and his Critics. By David L. Hull. Pp. xii+473. (Harvard University: Cambridge; Oxford University: London, September 1973.) £9.25.

ONE might well ask whether a collection of the reviews of Darwin's *Origin of Species*, written shortly after 1859, could still be of any interest. Even a quick perusal of this volume answers this question in the affirmative; it shows how fascinating these reviews are and how amazingly pertinent to the present day. Even though written by scientists—contemporary reviews by clergymen are not included—they deal not only with questions of scientific evidence but raise a number of timeless problems such as the relation between science and a belief in the supernatural, questions of the correct method and philosophy of science, of the relations between biology and the physical sciences, and of the nature of scientific revolutions.

The Darwinian revolution occupies a unique position among scientific revolutions because, far more than any others, it caused a dramatic upheaval in the thinking of man. Only this can explain the bitterness, indeed sometimes downright nastiness, of some of the reviews. By his explicit analysis of all aspects of the diversity of the living world, Darwin forced every thinking reader into the uncomfortable position of having to make a choice in favour of one of the only three possible causal explanations of the living world: (1) continuing creation, that is the everlasting intervention of the creator in replacing species and faunas that had become extinct and in creating ever-new adjustments and adaptations; (2) a belief in the existence of evolutionary laws with a built-in teleology ordained at the

time of creation, that would lead to ever greater perfection and adaptation, and to an orderly replacement of faunas in the geological sequence, and (3) a strictly non-teleological evolution, governed by random variation and natural selection, without any recourse to supernatural intervention, even at the beginning.

To accept the third of these interpretations meant rejecting the other two. Thus, the Darwinian revolution was not merely the replacement of one scientific theory by another, as had been the scientific revolutions in the physical sciences, but rather the replacement of a world view, in which the supernatural was accepted as a normal and relevant explanatory principle, by a new world view in which there was no room for supernatural forces. For the devout this meant a world without God, and such a view was heresy if not blasphemy.

Even though the present volume limits itself to sixteen reviews by scientists, the defence of the view that the world is the result of creation and governed by finalistic laws is prominent in each of the twelve reviews critical of Darwin. The reviewers are particularly stung by the silent implication of Darwin's thesis that it is unscientific to believe in supernatural causation. Hence their strenuous efforts to prove that Darwin himself is unscientific. Forever they repeat the claim that Darwin provides no proof for his manifold assertions, ignoring the fact that they were employing double standards, since Darwin's probabilistic evidence was immeasurably stronger than their own assertions of continuing creation. Rather remarkably, about half of the opposing reviews were authored by physicists, mathematicians, or other non-biologists. Their arguments often reveal an extraordinary ignorance of biological facts which they attempt to

compensate for by accusing Darwin of having violated "the true method of science", that is a strictly inductive approach. Hull, a philosopher, treats this problem in detail in a seventy-five page introduction. He deals very perceptively with the role of philosophical concepts and methods in the Darwinian revolution, as they relate to essentialism, teleology, and the inductive method, and brings out impressively to what extent Darwin was ahead of his contemporaries even in these theoretical matters. Nothing could be more wrong than the immemorial assertion: 'Darwin was no philosopher'. Indeed, it was his philosophical rethinking which permitted Darwin to consider species as populations rather than as essences, a formulation that was the prerequisite for the adoption of natural selection as the directing factor in evolution. His empirical philosophy allowed Darwin to be satisfied with the probabilistic nature of his conclusions (against complete "certainty") and to adopt the hypothetico-deductive method.

One must grant Darwin's opponents the validity of two of their objections. First, Darwin produced embarrassingly little concrete evidence to back up some of his most important claims. This includes the change of one species into another in succeeding geological strata, or the production of new structures and taxonomic types by natural selection. More importantly, although some of this has become apparent only in retrospect, Darwin either left totally unanswered certain serious problems like the origin of life and of new genetic variation, or he was himself confused about the problem as with respect to speciation, to the nature of variation, and to the role of isolation.

How far Darwin was nevertheless ahead of his contemporaries is clear not

only from the opposing but also from the supporting reviews (Hooker, Carpenter, Fawcett, and Wright). Since they also rejected supernatural intervention, they felt that Darwin's explanation was by far the best available one. But even these supporters were, on the whole, not too comfortable with natural selection. Nor were they thinking truly in terms of variable populations. To shift over to Darwin's radically new thinking was obviously difficult for anyone who had been raised in an era of creationism and essentialism.

The length of the reviews astonishes

Peacock water clock

IBN AL-RAZZAZ AL-JAZARI culminated the Muslim engineering tradition of the twelfth century. One of his mechanical devices was this clock which, with its decorations ran on water power. Water from an ornamental pool fell into a tipping bucket which filled and tipped every half hour. Hence by a system of pulleys the time on the clock face was changed, a peacock and a peahen were rotated, and the peacock whistled. The illustration shows another part of the machinery: a water wheel which in turning caused two young peacocks to 'quarrel'. The crank in the left-hand arm means that the chicks were tilted together or apart by the turning of the wheel. Al-Jazari's *Book of Knowledge of Ingenious Mechanical Devices* is translated and annotated by Donald R. Hill. (Reidel: Dordrecht and Boston, December 1973.) Dfl. 240; \$96.00.

a modern scientist. They average nineteen printed pages, even though the longest reviews (mostly of book length) by von Baer, Flourens, Kölliker, and Mivart are not included in this anthology (but short ones by von Baer and Mivart are). A book review in Darwin's day was an opportunity for the reviewer to write an essay on the subject matter of the book. Other reviews which were not included are listed in the bibliography.

The volume, in addition to reviews by eleven British authors, also includes five by foreign ones (Bronn, Pictet, von Baer, Wright, L. Agassiz). Curiously, Darwin was received much more favorably in America and Germany than in Britain. *Naturphilosophie* and a wave of extreme materialism had prepared for Darwin's enthusiastic reception in Germany. Unfortunately, however, Darwin was at once used as an ally in the fight against clericalism, particularly by Haeckel, and this rapidly led to a rather violent reaction, as reflected in the review by K. E. von Baer.

Hull has done a splendid job in editing these reviews. Each review is preceded by excerpts from Darwin's copious correspondence which deal with the reviewer, or more specifically, with the impact the review had had on Darwin. The editor then provides a concluding essay for each review in which the more important biographical details of the reviewer are presented, together with an analysis of his major arguments. The volume concludes with a detailed bibliography and a most helpful index. All in all an important and most stimulating contribution to the Darwin literature.

ERNST MAYR

The political scientist

Liberation and the Aims of Science: an Essay on the Obstacles to building a Beautiful World. By Brian Easlea. Pp. xiv+370. (Chatto and Windus, for Sussex University: London, November 1973.) £5.50 boards; £2.50 paper.

OVER the years, well meaning scientists and educators have fostered various 'integrating' or 'bridging' studies of natural science; and they have subsequently been disappointed when the intended purveyors of wisdom revert to type and become specialised research workers. As the title of this book proclaims, the author, a lecturer at the University of Sussex, has retained the courage of his convictions. Some may take this book as evidence for the blessings of pedantry. Others may see it (and the course it summarises) as providing a healthy dose of politics to science students; it might convert them to radicals, or at least to more self-aware (and hence effective) servants of the system.

In structure the book is a very thick sandwich: rather more than a third in the middle is on politics, mainly contemporary. The beginning is a very good exposition of the Popperist-Kuhn debates, with well developed examples from the Copernican revolution and non-relativistic solutions to the electrodynamics crisis of the early twentieth century. Both these examples point up the role of judgement in the acceptance of scientific theories, and the impossibility of any simple formula for validation. In this aspect the author's philosophy of science moves towards Polanyi.

Having established "commitment" as central to scientific work, the author uses it to introduce his analysis of social philosophy. He briefly studies Adam Smith, John Stuart Mill, Karl Marx and Alfred Marshall from this point of view, showing that "commitment", while explaining much about a thinker, is not necessarily in contradiction with the "objectivity" of his analysis. Keynes and his ideas are studied at greater length, and the section concludes with an exposure of "objectivity" in the social sciences.

The argument then moves to society itself, providing a Marxist critique of American capitalism and neo-colonialism. There is a new contemporary relevance in the argument by Heilbroner (quoted here) that although imports from the "underdeveloped" countries to ourselves might be small in proportion to the total, they act as "vitamins" to the economy. Since we are unlikely again to be so casual and patronising about our indebtedness to the poor nations, it is salutary to be reminded how recently such an attitude was shared by all but the radical fringe. The political discussion concludes with "Socialism in Crisis", showing all the warts but blaming them all on the unfortunate persistence of capitalism. Had the author provided an anarchist critique of socialism to match his socialist critique of capitalism, this part of the book would have been much enriched.

The book returns to science for its final quarter; here the critique is mixed socialist and eco-romantic. Easlea gives a fine survey of the "counter-culture", and a reminder of moral weaknesses in the history of the atomic bomb. Very near the end of the book is an analysis of J. D. Bernal's essay of 1929, *The World, the Flesh and the Devil*; showing the marriage of reductionist and Faustian themes that formed the basis of his commitment. As a man of influence in his century, and a late representative of a tradition still dominant, Bernal provides a most useful example. By contrast, Easlea believes in a beautiful world where science would be play, following William Morris more than Karl Marx.

Easlea's humanitarian commitment, translated into a certain orientation in politics, is overwhelmingly strong. Yet it does not destroy his objectivity; he is generous to all but the most reprehensible of his opponents and freely admits weaknesses and difficulties in the causes he holds as good. Any scientist browsing through it (starting with the excellent resumé at the end, a feature to be praised and emulated) will occasionally find himself shocked and annoyed, sometimes lost in an unfamiliar area of the author's broad competence, but never bored and frequently stimulated. The imposition of intellectual discipline on an intense personal vision has succeeded in this case; those who know how hazardous an operation this is, can congratulate the author on his achievement.

J. R. RAVETZ

IQ and inequality

I.Q. In the Meritocracy. By R. J. Herrnstein. Pp. x+193. (Allen Lane: London, November 1973.) £2.50.

Inequality: A Reassessment of the Effect of Family and Schooling in America. By C. Jencks. Pp. xii+399. (Allen Lane: London, 1973.) £5.00.

JENCKS and Herrnstein present two interpretations of the problem of inequality. Whereas Jencks is primarily concerned with the sources of individual differences in access to the educational, social and economic benefits of American culture, Herrnstein is more concerned about the less immediate consequences of biological inequality for social structure in a meritocracy. Both authors base part of their work on what they regard, individually, as acceptable models for variability in intelligence. To some extent their models differ, consequently their overall assessments of the role of intelligence also differ. Herrnstein, partly because he has adopted a model in which there is considerable genetical variability for IQ, affirms the social relevance of IQ measurements. Jencks, partly by his acceptance of a model in which genetical differences are less important, suggests that the contribution of genetical variation in IQ to traits that have social consequences is proportionately less than is sometimes supposed, although more than many would admit. The authors seem to differ in their interpretation of data, the veracity of which they both seem to accept. Such disagreement as exists therefore, stems not from differences in their attitude to the data, but from differences in analytical procedure.

Herrnstein does not attempt to analyse data. He has accepted a model based on

Jinks and Fulker's biometrical genetical reanalysis of some of Burt's correlations for IQ. Although on this model some 80% of the variation in IQ may be attributed to genetical variation, a substantial part of this is due to the non-fixable contribution of dominance and to the increase in genetical variability arising from assortative mating. Jencks, on the other hand, provides a detailed reanalysis using the method of path coefficients and argues that the heritability of IQ is nearer 45%. In addition, he claims that different estimates of 'heritability' are obtained from different degrees of relationship and that there may be positive covariation between genotypic and environmental deviations: the so-called 'double advantage' phenomenon. Although Jencks suspects the presence of dominance, he does not treat the matter analytically, an omission which, as we shall see, could explain some of his unusual conclusions.

A fundamental weakness of Jencks's approach is his failure to make explicit the mathematical relationships between genetical paths in different pedigrees (path diagrams) and between different paths of the same pedigree. For example, not all the numerically feasible solutions given by Jencks in Table A-5 for the relationships between his paths g (between parental and offspring genotype) and h^2 (broad heritability) are genetically sensible. Genetical theory indicates that only solutions in which $g \leq \frac{1}{2}h^2$ for the parent-offspring covariation are genetically sensible. His failure to specify these restraints means

that equal weight is given to sense and nonsense answers. When we consider the amount of assortative mating and make allowance for the possibility of dominance the only estimates of h^2 consistent with a genetical model lie between 0.59 and 0.76 corresponding with Jencks's estimates of g of 0.25 and 0.30. Rather than supporting a lower heritability, therefore, on this basis alone Jencks's data are consistent with the value obtained by fitting a biometrical genetical model to all the data simultaneously (see Tables 1 and 2).

A further weakness of Jencks's approach is his failure to deal systematically with dominance. This can be seriously misleading for a trait such as IQ for which there seems to be considerable non-additive genetical variation. Dominance could account for much of the apparent heterogeneity between estimates of heritability obtained from different degrees of relationship. The ratios given by Jencks do not estimate the broad (or narrow) heritability in the presence of dominance and the inconsistencies to which he refers do not reflect haphazard inconsistencies in the data but the ordered departures from simple additivity which, within the limits of sampling variation, depend on the presence of a considerable amount of dominance (see Table 2).

Analytically, Jencks's procedure is inefficient. He estimates parameters from one set of data and uses these to correct estimates from other sets. This is not merely inelegant, it also yields the poorest approximations of the param-

eter estimates and could lead to the rejection of an otherwise acceptable model. Jencks may have been wise in eschewing statistics in a tentative analysis of heterogeneous data, but some attempt to use statistical criteria could have led to a more objective assessment of the confidence which others could place on his conclusions.

We have, therefore, subjected the correlations used by Jencks to a biometrical genetical analysis in which the expectations in terms of a model are fitted to all the statistics simultaneously so that the parameters are estimated from the full data set and the agreement between the observed and expected statistics after fitting the model can be tested. A parallel analysis of the full table of correlations given by Burt, only part of which has been hitherto analysed by these methods, has been carried out for comparison.

The data are given in Table 1. Normally we prefer to work with raw variances and covariances rather than correlations because the latter are far from normally distributed even in quite large samples and because valuable information is lost by standardisation to unit variance. A weighted least squares analysis of the two sets of correlations was conducted which has the advantage of efficiency and provides (given normality)

a test of goodness of fit of the model. Because of assortative mating the model is non-linear and a more complete discussion of the method and the model will be published elsewhere. By adopting a weighted least squares approach we have ensured that statistics based on small samples are given proportionately less weight in determining the final solution. As a result, the small samples of monozygotic twins reared apart, which have been criticised on several grounds, play a relatively small part in our analysis. In fitting the model simultaneously to a wide range of relationships we have evaluated its predictive validity in a broad context. Our model involves five parameters: an additive genetical component (D_R), a dominance component (H_R), a common environmental component (E_c), the marital correlation (μ) and the correlation between the additive genetical deviations of spouses (A). A sixth component, the specific environmental component (E_1), is obtained by difference at the end of the analysis.

This model differs from that quoted by Herrnstein by making E_c an environmental component shared by parents as well as offspring. This may lead to underestimation of D_R and consequent overestimation of H_R and A if unjustified. Making E_c applicable

purely to offspring results in a slightly poorer fit to Jencks's data. Our model differs from Jencks's in assuming that placement effects and the covariation of genotype and environment are negligible. The former assumption will lead to the overestimation of E_c in the event of placement correlations being significant, the latter assumption to failure of the model in the event of genotype-environment covariation being substantial. Such covariation is most easily detected by the analysis of raw variances. Jinks and Fulker were unable to detect it in their analysis of variances but the relevant sample sizes were small. Any analysis which does not make provision for an adequate test of the model may well discount some dominance variation as positive genotype-environment covariance and *vice versa*.

Burt's correlations are for final assessments and those given by Jencks include his corrections for unreliability and for differences between sample means. We have retained these corrections in order to yield results which are more directly comparable with those of Jencks. By treating such estimates as raw correlations we have, among other things, overestimated their precision and consequently regarded the analysis as more sensitive than is

really the case. But whatever else may be said about the quality of the data, their quantity is such that our estimates are fairly precise and our test of the model fairly sensitive.

Table 2 gives the weighted least squares estimates of the parameters. The standard errors are approximate and assume that the deviations between observed and expected are small enough to be ignored. The expected values obtained by fitting the model to the data are given alongside the corresponding observed values in Table 1. Although individual deviations are sometimes large, the overall weighted sum of squared deviations, which is χ^2 if the observations are normal, is small in relation to the total weighted sum of squares of the observations.

Although the two data sets differ with respect to μ and E_e they are consistent for the estimates of D_n , H_n and A . There is some support for Jencks's conclusion that the heritability of IQ is apparently lower in the American studies than in Burt's British study. The best estimate of the broad heritability of IQ scores, however, for Jencks's data, is 68% which is 50% higher than the estimate Jencks has accepted. Since the model fits his data we cannot support his conclusion that the data give a heterogeneous picture of the genetics of IQ. Neither can we conclude that the data provide any evidence of genotype-environment covariation when proper allowance is made for dominance. On the contrary, when we allow for such covariation in the simplest way by adding to our five-parameter model one further parameter, r_{ge} , to specify the contribution of this covariation, no significant improvement in fit of the model to the data set is achieved. Furthermore, the weighted least squares estimate of r_{ge} is -0.31 with an approximate standard error of 0.20 . This is not only non-significantly different from zero but in so far as it is negative it has the opposite sign to the covariation postulated by Jencks in his model.

A small anomaly in the results of our analysis of Burt's data is that A is numerically (though not significantly) greater than μ . This anomaly is removed by stipulating that parents and offspring do not share developmentally important environmental features. The correlation between foster parent and adopted children then has to be accounted for partly by placement.

The analyses strikingly confirm Jinks and Fulker's conclusion regarding the importance of dominance variation. Even if we make allowance for possible overestimation this can best be explained only if dominance deviations at individual gene loci are large or if increasing dominant alleles are more frequent than their recessive counterparts. Coupled with the evidence for inbreeding depression, this suggests that IQ displays the pattern of genetical variation associated with a fitness character, that is, a trait which has been subject to a history of directional selection for increasing IQ score. Whatever else may be said about its social significance, IQ is clearly a trait of biological relevance.

Because much has already been made of the relatively low estimate of heritability argued for by Jencks, we have concentrated on the small part of his book devoted to this subject. We felt that it was important for the continuing discussion to establish that Jencks's American data do not in fact give a picture for the genetics of intelligence which differs in principle from that which has long been apparent from British studies. In so doing we have not done justice to the scholarly presentation and thought-provoking discussions contained in both Herrnstein's and Jencks's books, which have more in common than perhaps either author would admit to, and little that we would wish to dissent from. We are agreed that there are individual differences for IQ, that only a proportion of these differences might be removed by environmental manipulation, and that the

features of the environment that would require modification to achieve this have still to be identified. Those concerned with inequalities in our society might just as well resign themselves therefore to the fact that individual differences for IQ at more or less their present level will continue to be an important factor. In these circumstances, those who wish to see progress towards a more equitable society should turn their attention to the means of ensuring that the greater social and financial rewards of our society are not reserved for those who, whether through their genotype or environment, have a higher than average IQ.

L. J. EAVES

Plan by computer

Computers and Socialism. By Stephen Bodington. Pp. 245. (Spokesman: Nottingham, 1973.) £4.00.

THE book considers, in broad terms, the impact that computers could have on society in the foreseeable future. Descriptions are in non-technical terms, and are aimed at the intelligent layman with an interest in computers and economics.

A chapter is devoted to an appraisal of modern computer technology. Although in the thirty pages involved one could hardly expect a complete survey, there are some omissions. Little is said of the difficulty in constructing large software systems, in spite of the fact that software now dominates hardware in cost terms. It is rapidly becoming apparent that our capacity to control such large systems is a limiting factor in the development of computers as a whole.

A major part of the book is devoted to the thesis that computers should permit better planning by provision of more accurate information. As is noted in the book, such changes are already taking place with the aid of linear pro-

gramming, PERT and even faster conventional accounting techniques. Several computer-based management information systems are now being sold commercially. The success of such systems largely depends upon the presentation and analysis of the basic information provided. Bodington looks forward to accurate economic modelling as the major planning tool. He hopes that a wide dissemination of information from such models will permit a decentralised power structure, although the political mechanism for achieving this is not discussed.

A surprising omission, in view of the lengthy discussion of modelling methods, is that of the world models of Forrester and Meadows. The significance of such models could be greatly increased if their reliability could be improved. But it does not seem likely that economic systems can be predicted with any accuracy (as the wide fluctuations in the basic commodity markets tends to show).

The book is well produced, although some of the formula and computer material is not correctly set. The subject matter is well presented, and since it is one of the first books in this area, it makes a useful addition to a library. I hope, however, that more penetrating analyses of the impact of computers will soon be available.

B. A. WICHMANN

Archaeologists entertain

Archaeological Theory and Practice. Edited by D. E. Strong. Pp. xiv+308. (Seminar: London and New York, August 1973.) £5.50.

THIS book is a *Festschrift* offered by his colleagues on the staff of the Institute of Archaeology in London to its director, Professor W. F. Grimes, after his seventeen years of service in that position. It is not, therefore, a survey of the theoretical structure of archaeology, as its title might imply, but an agreeable and wide ranging anthology, reflecting the considerable scope of interests of the staff of the institute, from Roman London (where much of Grimes's own work was carried out) to islands in southeast Asia, and from Acheulian hand axes to mediaeval technology. A particularly welcome feature is the inclusion of articles on photogrammetry and photographic techniques by staff in the Departments of Archaeological Photography and Archaeological Drawing and Survey.

Among the themes underlying this wide breadth of interest, a concern for environmental archaeology is perhaps the most prominent. Two further contributions are of very wide methodological interest. Professor J. D. Evans, Grimes's successor as director, writes

lucidly on his system of sherd analysis and sherd counts which he has used on the pottery from neolithic Knossos in Crete to very good effect, putting his findings on a firm quantitative basis. And M. H. Newcomer and F. R. Hodson describe a method here termed "constellation analysis", which permits the elegant comparison of different classifications of a given body of material, each classification being based on different criteria. A quantitative comparison is thus afforded of the results obtained from several independent approaches to the same set of data. In the example discussed the method has been applied to Newcomer's data on the burins from the upper palaeolithic levels at Ksar Akil in the Lebanon.

The human, almost anecdotal, interest of two contributions in particular catches the interest, for they are both at the same time contributions to scholarship. W. M. Bray, in "A page of *Punch*", reproduces a poem entitled "Monkey-ana". This is a lampoon, published in 1861, of the participants in the great British Association debate held in Oxford the previous year, when Huxley clashed so memorably with Bishop Wilberforce. In his discussion Bray brings out both the warmth in the scholarly world of the evolution controversy and, in an illuminating way, the extent to which the debate was reflected in the popular press as a whole.

The second of these delightful disquisitions is by the editor of the volume, Professor D. E. Strong, whose sad and sudden death in Turkey was reported shortly after the publication of this book. Professor Strong always accompanied his wealth of scholarship in Roman archaeology with a very modern wit, and in "Roman museums" he considers the Romans as connoisseurs and collectors of ancient art with a very contemporary awareness. The parallel with the pretensions and preoccupations of our own times is never explicitly drawn, but lingers engagingly below the surface. As scholarly as it is entertaining, this is a splendidly original and human contribution to a varied and wide ranging book.

COLIN RENFREW

Maths of Ch'in Chiu-shao

Chinese Mathematics in the Thirteenth Century: The Shu-shu chiu-chang of Ch'in Chiu-shao. By Ulrich Libbrecht. Pp. xxxi+555. (MIT: Cambridge, Mass., and London, 1973.) £11.25.

"ORIENTAL mathematics may be an interesting curiosity, but Greek mathematics is the real thing" (G. H. Hardy, 1940). Hardy's words were written before Needham's *Science and Civilisation in China*. The book under review is an

instalment of the volumes of detailed work needed before a successor to Needham, or at least a development of his mathematical section, can be attempted. But I don't think that either Needham or Libbrecht would have persuaded Hardy to change his views. The Greeks, lacking a decent notation for computation, developed mathematical ideas in a geometrical context. The ancient Chinese, having developed a notation of decimal place-values which allowed them to compute pretty efficiently and competently, developed their mathematics in a practical (though I know of nobody as practical as Archimedes) and pedestrian manner.

Perhaps changes here since Hardy's

In memoriam

GRAFTON ELLIOT SMITH (1871-1937) was a man of many parts; he was first and foremost an anatomist with a speciality for comparative neurology; later in life he became a determined and outspoken contributor to debates on man's physical and cultural evolution. These and the other interests of this extraordinary scientist, were reflected in the contributions to a symposium organised in November 1972 in commemoration of the centenary of Elliot Smith's birth by the Anatomical Society and the Zoological Society of London.

In the proceedings just published (*The Concepts of Human Evolution* (Symp. zool. Soc. Lond. No. 33) edit. by Lord Zuckerman (Academic: London, January 1974) £10.30; \$29.00), Lord Zuckerman—one of the small group of anatomists alive today who both knew and worked with Elliot Smith—introduces the man; there follows a medley of other relevant contributions and the volume ends with a thought-provoking and controversial session on "Elliot Smith, Egypt and Diffusionism".

death throw some light on this matter. The development of the computer is tending to strangle mathematical thinking among all but the brightest of its users: so one should not be surprised that the computational efficiency of Chinese mathematics tended to inhibit mathematical inventiveness except in the case of brilliant individuals not part of the State's official mathematical bureaucracy. Ch'in Chiu-shao (probably 1202-1261) was one of four such now known to have lived, and worked independently, within half a century. The *Shu-shu chiu-chang* is his mathematical legacy—a treatise with problems and answers intended for practical use. Ch'in, a soldier of fortune and administrator, was a colourful and dubious character who will doubtless, when Chinese mathematics is better known in the West, be included in the gallery of such characters with, for instance, such old friends as Cardano and Galois. The treatise is in nine chapters: apparently a significant structure already used in the *Ch'iu-chang suan-shu*, the standard textbook which in Ch'in's time had already been in use for about a thousand years (less than the time during which Euclid dominated the West!). The contents of Ch'in's book are in many ways similar to the earlier one, but the problems are harder and the fruit of a considerable individual development. But there are some things not to be found in the earlier work. For instance an algorithm for solving the so-called Chinese Remainder Problem (for which Ch'in is at present best known) is the most important. There is also what Dr Libbrecht, doubtless correctly, takes as clear evidence that Ch'in had completely anticipated Horner's method for the solution of equations. Ch'in was apparently so pleased with this method that he deliberately and unnecessarily complicated the solution of one problem in order to demonstrate his virtuosity with an equation of the (unnecessarily high) tenth degree.

Ch'in's book was intended, as the conventions of Chinese mathematics at the time required, as a practical treatise and not as a mathematical text as we know it: it was rather a cookery book, but the recipes were subtle and based on much deeper mathematical thinking than was expressly used in the text. It is for this reason that Dr Libbrecht's research into the book and its background is so valuable. At first sight Libbrecht's book is not an attractive work: it is written as a serious and scholarly study, not for easy reading, but to serve as a start for the accumulation of the knowledge necessary to write a more easily read work. But the book grows on one with deeper acquaintance; its integrity and thoroughness are totally convincing. Clearly Dr Libbrecht's second career as an ori-

ental scientific historian (his first was as a teacher of mathematics) is destined to be brilliant and rewarding. The chapter on the socioeconomic information to be derived from Ch'in's book raises high hopes of interesting future developments.

D. B. SCOTT

Sussex replies to Rome

Thinking about the Future: a Critique of the Limits to Growth. Edited by H. S. D. Cole, C. Freeman, M. Jahoda and K. J. R. Pavitt. Pp. 218. (Chatto and Windus (Sussex University): London, 1973.) £3.00.

Has the development of the energy crisis in the past few months strengthened the argument of Meadows's *Limits to Growth*, and weakened the trenchant critique of it, *Thinking about the Future*, by the University of Sussex Science Policy Research Unit team?

The fact that oil reserves are finite has no direct bearing on the Arab use of the oil weapon. It has depended simply on Arab states controlling a proportion of existing production capacity large enough to control the market. The long lags in exploration and drilling and the provision of transport elsewhere has made their action effective in the short term. It has at a stroke, and by design, raised oil prices to the level where as Surrey and Bromley point out in chapter 8, alternative sources of energy become economic. They further remarked, writing early in 1973, "In addition to the political uncertainties surrounding the future of Middle Eastern oil, some of the small Arab states which are large oil producers may decide to conserve their oil reserves until prices rise, rather than accumulating large foreign exchange reserves which are subject to depreciation by inflation and major currency re-alignments".

Peccei, the founder of the Club of Rome which sponsored *Limits to Growth*, has said that the political factors omitted from the study exacerbate the problem, and these political factors have brought forward the threat of doomsday. But it is equally possible to argue that political factors, as one aspect of the flexibility of human response, have brought forward action on energy supplies in time to deal with supply limitations before they became physically acute. Politics, for all its frustrations, can make society more adaptive than its dynamic systems model, not less.

Likewise within the United Kingdom, whatever the political and economic consequences of the miners' industrial action in the short term, the long term effect can be to secure a more even distribution of wealth and power within one industrial society, thus averting the

build-up of greater tensions in the future.

This is not to argue that all is for the best in the best of all possible worlds. But it does raise the question whether on population, food, resources, and pollution *The Limits to Growth* addressed the right problems at all.

The Sussex team, taking *The Limits to Growth* at its own valuation, reviews the evidence used and the structure of the model, and concludes they do not justify the conclusions drawn. As a bonus they put *Limits* in its ideological perspective, against the background of the history of economic thought, the movements of environmentalism and technocracy, and the processes of social change. On evidence and ideology the critique is strong. Experts in particular fields will disagree about the realism of some of the assumptions tried by the Sussex team but they will also criticise those made by Meadows. On the methodology of modelling systems of uncertain, tenuous and changing structure however, the Sussex critique is less sure footed. *The Limits of Growth* is deficient in having ignored the hard won experience of econometrics, stochastic estimation and control theory, and more general adaptive systems. Forrester and Meadows quite fairly argue that this systems apparatus as it stands cannot draw conclusions from the sparse information available on world environmental problems. But combined with a perception of the real world—Meadows's or anyone else's—it does give a more realistic approach to practical policy making than does the crudities of "systems dynamics", which is no more than the solution of simultaneous dynamic equations. The reason for this is that a wider systems theory illuminates the behaviour of indeterminate systems partially controlled with partial knowledge of system behaviour.

The Sussex critique does not touch this problem of adaptive behaviour beyond pointing to other factors in social change. There are these other factors, but their effect manifests itself in the indeterminacy, not the incoherence, of physical systems when viewed as systems on their own. But the physical systems are important enough to warrant the fullest analysis. For example the Sussex team is well equipped to analyse the evidence on the time lags and uncertainty in industrial innovation, a crucial factor in the ability of industrial society to adapt and survive. Perhaps without the inhibitions of criticising other work, but stimulated by the courage, even the sheer impudence, of *The Limits of Growth*, the Sussex team will contribute further to the vast task of building a genuine discipline of social systems analysis.

J. W. BRAY

PHYSICAL SCIENCES

Splitting atoms

Nuclear Fission. By Robert Vandebosch and John R. Huizenga. Pp. xii+422. (Academic: New York and London, November 1973.) \$29.50.

Fission is one of the most peculiar and important phenomena in the whole of nuclear physics. If the constants of nature had been slightly different it could not have occurred at all, and the history of the world after 1940 would have been completely changed. Yet in spite of its great practical importance it occupies a very peripheral position in nuclear physics itself. Concepts from the rest of nuclear physics are used to understand fission, but until recently studies of fission told us very little about the nucleus. By far the most important effect of fission on nuclear physics was indirectly through its applications. These led to the growth of vast industries and this so stimulated nuclear physics and made such large resources available that the subject is now several decades further advanced than it would have been if fission had never taken place.

One of the results of this situation was that although most people almost identified fission with nuclear physics, most nuclear physicists neither knew nor needed to know much about the fission process.

This situation has changed dramatically in the past few years with the discovery of a whole range of phenomena including shape isomers, intermediate structure and the double-humped potential barrier. These exciting developments have greatly stimulated research on fission and a much more detailed understanding of the process is now being obtained. From an entirely different direction the technical advances in heavy ion physics have made it possible to study the collision of heavy nuclei with each other, and thus to investigate the complementary fusion process.

The new knowledge has now consolidated to the extent that an extended survey is timely, and this book by Professors Vandebosch and Huizenga fills the need admirably. Both authors have studied fission for many years and are in a position to present a detailed and authoritative account of present knowledge.

After a brief historical survey, they summarise the liquid drop and single particle models, and their application to nuclei of increasing deformation. The Strutinsky model combines the two by superposing the variations in nuclear properties from nucleus to nucleus due to their shell structure on the average

behaviour given by the liquid drop model to give a detailed and accurate overall theory. This model is described in detail and applied to the systematisation of fission barrier heights and other features of fission.

Subsequent chapters consider the present state of knowledge on spontaneous fission, fission widths obtained from neutron resonance studies, the properties of low-lying levels of transition nuclei, the angular distributions of the fission fragments as a function of excitation energy and the competition between fission and neutron emission.

Fission can be induced by photons, deuterons, tritons and many other particles, and a study of the corresponding cross sections can give information about the fission potential barrier. Much is being learnt about the way a nucleus deforms on the way to fission, and the mass and density distributions as the separation takes place. The kinetic energy released in fission is of both practical and theoretical interest, as well as the distribution of mass and charge among the fission fragments. All these aspects are carefully described, and the three final chapters are devoted to the prompt neutrons from fission, ternary fission and the gamma rays emitted from the primary fission products.

Full references to relevant researches are given at the end of each chapter, enabling particular topics to be followed up in detail. This is a well balanced and comprehensive survey of our present knowledge of fission that fills a real need. It will be of great value not only to those studying fission itself but also to other nuclear physicists who find that due to its growing academic importance they now have to repair a conspicuous gap in their knowledge.

P. E. HODGSON

All people of the earth

Implications of Continental Drift to the Earth Sciences. Edited by D. H. Tarling and S. K. Runcorn. Vol. 1, pp. xvi+1-622; vol. 2 pp. xiv+623-1184. (Academic: London and New York, April 1973 and November 1973.) Vol. 1 £13.80; vol. 2 £13.00.

ON the face of it, Earth scientists can hardly be accused of failing to respond to social need, defined in this context as material demand. Geologists, geophysicists and geochemists have long been associated with prospecting and the discovery of minerals and fossil fuels; their brethren with eyes on higher things are now achieving ever greater success in the understanding and prediction of

atmospheric phenomena, much to the benefit of agricultural and other pursuits; and a careful search might even show that something has been contributed to man's physical welfare by palaeontologists. But at the other end of the spectrum there is another, rather more glamorous and generally quite distinct Earth science community whose task it has been to elucidate the nature of the Earth for its own sake. In the purely intellectual sense the achievement of the latter group has been immense; to its various members we owe what has come to be known as the revolution in the Earth sciences and all that it implies in vindication of Thomas Kuhn's paradigmatic hypotheses. On a less esoteric plane, however, the material benefits which a society increasingly suspicious of science might conceivably expect from the scale of its investment have been somewhat less apparent.

For this last reason, the Newcastle upon Tyne (April 1972) conference on the "Implications of Continental Drift to the Earth Sciences" was, despite titular ambiguity and curious grammar, welcomed by some as a sign that the purer Earth scientists were beginning to perceive their social responsibilities. On the whole, however, this proved to be a naive expectation even though in other respects the conference was rightly pronounced a success. Something like 20% of the papers presented were devoted to background reviews of palaeomagnetism and sea floor spreading; about 35% dealt with the palaeontological, palaeogeographic and palaeoclimatic implications of these phenomena; and a similar proportion was concerned with geological implications in terms of continental and oceanic evolution, rifts and rift margins, and continental edge structures. What these figures and headings demonstrate on the credit side is that Earth scientists of all disciplines are now talking to each other to a quite remarkable degree, almost all apparently having accepted the general validity of the new global tectonics and the need to interpret both new and old data in those terms. But it is equally clear, at least as far as this conference was concerned, that few people are yet able or willing to see their work in terms of its natural resource implications. Of the 87 papers involved only six—a disappointingly low proportion—were specific enough to be classified under the general heading of "economic significance", although it could be argued with some justice that many of the more geologically inclined presentations form the essential base for subsequent, more applied studies.

The two books under review are a record of the proceedings of the New-
